One of the more recently hired secretaries objected strongly to being hypnotized. She suffered regularly upon the onset of menstruation from severe migrainous headaches lasting three to four or even more hours. She had been examined repeatedly by the medical service with no helpful findings. She usually retired to the lounge and "slept off the headache," a process usually taking three or more hours. On one such occasion she had been purposely and rather insistently forced to take dictation by the author instead of being allowed to retire to the lounge. Rather resentfully she began her task, but within 15 minutes she interrupted the author to explain that her headache was gone. She attributed this to her anger at being forced to take dictation. Later, on another such occasion, she volunteered to take certain dictation which all of the secretaries tried to avoid because of the difficulties it presented. Her headache grew worse, and she decided that the happy instance with the author was merely a fortuitous happenstance. Subsequently she had another severe headache. She was again insistently requested by the author to take some dictation. The previous happy result occurred within 10 minutes. Upon the occurrence of another headache she volunteered to take dictation from the author. Again it served to relieve her headache. She then experimentally tested the benefits of dictation from other physicians. For some unknown reason her headaches only worsened. She returned from one of these useless attempts to the author and asked him to dictate. She was told he had nothing on hand to dictate but that he could redictate previously dictated material. Her headache was relieved within eight minutes. Later her request for dictation for headache relief was met by some routine dictation. It failed to have any effect.

She came again, not too hopefully, since she thought she had "worn out the dictation remedy." Again she was given dictation with a relief of her distress in about nine minutes. She was so elated that she kept a copy of the transcript so that she could ask others to dictate "that successful dictation" to relieve her headaches. Unfortunately, nobody seemed to have the "right voice," as did the author. Always, a posthypnotic suggestion was casually given that there would be no falling asleep while transcribing.

She did not suspect, nor did anybody else, what had really been done. The author had made comprehensive notes of the incoherent verbigeration of a psychotic patient. He had also had various secretaries make verbatim records of patients' incoherent utterances. He had then systematically interspersed therapeutic suggestions among the incoherencies with that secretary in mind. When this was found to be successful, the incoherent utterances of another patient were utilized in a similar fashion. This was also a successful effort. As a control measure, routine dictation and the dictation of "undoctored incoherencies" were tried. These had no effect upon her headaches. Nor did the use by

others of "doctored" material have an effect, since it had to be read aloud with some degree of expressive awareness to be effective.

The question now arises, why did these two patients and those patients used experimentally respond therapeutically? This answer can be given simply as follows: They knew very well why they were seeking therapy; they were desirous of benefiting; they came in a receptive state, ready to respond at the first opportunity, except for the first experimental patient. But she was eager to be freed from her headache and wished the time being spent taking dictation could be time spent getting over her headache. Essentially, then, all of the patients were in a frame of mind to receive therapy. How many times does a patient need to state his complaint? Only that number of times requisite for the therapist to understand. For all of these patients only one statement of the complaint was necessary, and they then knew that the therapist understood. Their intense desire for therapy was not only a conscious but an unconscious desire also, as judged clinically, but more importantly, as evidenced by the results obtained.

One should also give recognition to the readiness with which one's unconscious mind picks up clues and information. For example, one may dislike someone at first sight and not become consciously aware of the obvious and apparent reasons for such dislike for weeks, months, even a year or more. Yet finally the reasons for the dislike become apparent to the conscious mind. A common example is the ready hostility frequently shown by a normal heterosexual person toward a homosexual person without any conscious realization of why.

Respectful awareness of the capacity of the patient's unconscious mind to perceive meaningfulness of the therapist's own unconscious behavior is a governing principle in psychotherapy. There should also be a ready and full respect for the patient's unconscious mind to perceive fully the intentionally obscured, meaningful therapeutic instructions offered them. The clinical and experimental material cited above is based upon the author's awareness that the patient's unconscious mind is listening and understanding much better than is possible for his conscious mind. It was intended to publish this experimental work, of which only the author was aware. But sober thought and awareness of the insecure status of hypnosis in general, coupled with that secretary's strong objection to being hypnotized—she did not mind losing her headaches by "taking dictation" from the author—all suggested the inadvisability of publication.

A second secretary, employed by the hospital when this experimental work was nearing completion, always suffered from disabling dysmenorrhea. The "headache secretary" suggested to this girl that she take dictation from the author as a possible relief measure. Most willingly the author obliged, using "doctored" patient verbigeration. It was effective.

Concerned about what might happen to hypnotic research if his superiors were to learn of what was taking place, the author carefully failed with this second secretary and then again succeeded. She volunteered to be a hypnotic subject, and hypnosis, not "dictation," was then used to meet her personal needs. She also served repeatedly as a subject for

various frankly acknowledged and “approved” hypnotic experiments, and the author kept his counsel in certain other experimental studies.

Now that hypnosis has come to be an acceptable scientific modality of investigative and therapeutic endeavor and there has developed a much greater awareness of semantics, this material, so long relegated to the shelf of unpublished work, can safely be published.

SUMMARY

Two case histories and a brief account of experimental work are presented in detail to demonstrate the effective procedure of interspersing psychotherapeutic suggestions among those employed to induce and to maintain a hypnotic trance. The patients treated suffered respectively from neurotic manifestations and the pain of terminal malignant disease.

Hypnotic Training for Transforming the Experience of Chronic Pain

Milton H. Erickson and Ernst L. Rossi

Unpublished dialogue between Erickson and Ernst L. Rossi, 1973.

E: You have a patient that comes to you for chronic pain. He has been in the waiting room and then comes into your office. You put him in a trance, tell him to walk back into the waiting room, leave his pain there, and come back into the office. Tell it to him as if you were telling him to take his jacket into the other room and leave it there.

R: You tell it to him that casually?

E: Yes. When he comes back you tell him, "Now I want to awaken you while your pain is still in the waiting room." You talk casually about various things, and when the hour is over you have him leave by the other door out of the office because he says he doesn't want to go back through the waiting room where the pain is. He doesn't know why he says that because he doesn't know he left his pain there.

R: I wonder if this is a form of literalness where the patient follows your casual suggestion and treats the pain as a reified or concrete thing that can be left behind like a jacket?

E: It is. But bear in mind that the patient's pain will seep back.

R: How do we prevent the pain from seeping back? You will recall the patient of mine who has the back pain. Her X-rays showed an organic source of the pain, and the medical recommendation was an operation to fuse her vertebrae. She comes into my office and goes into trance beautifully and becomes completely free of pain while with me. For a brief period of time, after awakening from the trance and while still in my office, she remains free of pain. Then it begins to seep back when she leaves the office. Now I would like to prevent that pain from seeping back so quickly. I've trained her in self-hypnosis so she can be free of pain by herself when in trance at home. It works for her while she's in trance. As soon as she comes out of the trance, however, her pain is there again. How can we extend the relief for her?

E: One of the best measures for teaching extended pain relief is to teach the patient to let catalepsy persist.

R: In the painful part of the body?

E: No!

R: In any body part.

E: You saw the demonstration I did with the visiting psychiatrists who did not believe they could experience catalepsy.

R: Yet they did experience it bit by bit and even discussed all their sensations in detail as they learned the cataleptic experience of an arm becoming rigid and immobile.

E: You establish a belief in catalepsy that can persist and resist the person's efforts to remove it.

R: You mean to actually let the patient leave the office and go about daily life with, say, a little finger cataleptic?

E: No, you let the catalepsy persist for some time in the office.

R: You have the patient test it to see how it lasts and to see that it can be a real and persisting experience even when he comes out of trance?

E: Yes, and then later you bring in an analogy with pain. You extend time by saying your catalepsy can extend 10 seconds just as it can last 11. If 11, then 12. If 12, then 14 seconds is possible. If 14, then 17 is possible. If 17, then certainly 27 seconds! You then extend that to a few minutes and eventually hours.

R: While the patient's hand is cataleptic?

E: Yes, you let him discover he can extend the catalepsy—but he can also lose his catalepsy. He can lose his pain, but he can also get it back. He can lose his catalepsy, but he can get it back. People can learn so simply to turn pain, catalepsy, or any other subjective experience on and off.

R: You give patients hypnotic training to extend in time just about any hypnotic phenomena they are skillful in experiencing. You then establish a new learning set (*dentero*-learning) for turning that subjective experience on and off. In dealing with the problem of chronic pain it would be especially useful to train the patient in whatever subjective phenomena would interfere with or transform the pain. Since most people are highly idiosyncratic in their personal psychosomatic interactions, this kind of hypnotic training for pain relief would always proceed on an exploratory basis. For some patients a hypnotic experience of warmth or coldness, numbness, pressure or itch, hallucinatory taste, smell, or whatever might be found useful in learning to displace or relieve in some way their pain. Pain relief by hypnosis is not some sort of vague magic; it is based on essentially irrational associative patterns, but it is very definitely a valid empirical process. With careful training it becomes a reliable way of cultivating and transforming all sorts of subjective experiences—including that of pain.

Hypnotically Oriented Psychotherapy in Organic Brain Damage

Milton H. Erickson

Reprinted with permission from *The American Journal of Clinical Hypnosis*, October, 1963, 6, 92-112. This article was published simultaneously in translation in *Ceskoslovenská Psychologie*, Prague, Czechoslovakia.

Ordinarily brain damage with continued evidence of organic changes and destruction presents a seriously difficult problem for psychotherapy. In the following case history a rather detailed report is given of the use of a multitude of psychological measures, forms of instruction, direct and indirect hypnosis, and the manipulation of patterns of responsive behavior and reactions, all to effect therapeutic gains after a failure of conventional medical and surgical procedures. Considerable detail is given in presenting this case history instead of summarizing it by a simple statement of pertinent medical facts. An effort is made in this more detailed account to give the reader the "feel" of the psychological as well as the organic picture that confronted the author, both of which had a determining role in the therapy he devised.

On July 20th, 1955, this 38-year-old college-bred woman who had been a brilliant student and who had a master's degree was returning with her husband and three children from a happy vacation trip. On the way she complained of a developing headache which rapidly grew worse and led to a state of coma.

She was hospitalized, and examination disclosed fresh blood in her spinal fluid, a right hemiparesis, a severe aphasia, and an aneurysm at the division of the left internal carotid artery just before its division into the middle and anterior cerebral arteries.

Treatment was conservative until August 2nd, when her symptoms became much worse and she developed sever hyperalgesia over her entire right side, which was diagnosed as a "thalamic syndrome." She was given numerous medications to control her pain, but since she appeared to receive no benefit, surgery was employed August 8th to clamp off the common carotid artery slowly and completely. This relieved her headache and some general symptoms but left some of her right-sided hemiparesis and hyperesthesia. A month later she developed extreme pain over her right side, which was diagnosed as "central in origin—the thalamic syndrome."

She had regained her ability to walk fairly well although unsteadily, but her increased thalamic syndrome pain and the failure of analgesic medication and sedatives led in a few months to hospitalization in a well-known clinic in January, 1956.

General examination there confirmed the previous diagnosis of thalamic syndrome, disclosed numerous additional neurological findings concerning right-sided muscular and

sensory dysfunction as well as the aphasia. The recommendation was offered that no further laboratory studies or general examinations were needed for diagnostic or other purposes. The previous failure of medications was noted, and the final recommendation was made that various untried experimental drugs might be considered. The prognosis offered was most unfavorable. This was rejected by the family, and in March, 1956, at her husband's insistence and because of his wife's completely vegetative course during her illness, she was admitted to another well-known neurological institute. The findings there confirmed the persistence of considerable hemiparesis, severe aphasia, and a continuance of the right-sided hyperalgesia. As in the previous neurological studies, she was found to have normal sensations and normal muscular functioning on the left side of her body. Her thalamic syndrome of generalized right-sided continuous pain and hyper-sensitivity was considered to have continued as possibly unchanged. No specific recommendations were made, and her prognosis was again stated as most unfavorable.

She entered a third neurological institute in June, 1956, and underwent neurosurgery for her thalamic syndrome. Report was made to her family physician that "we interrupted the spino-thalamic and quinto-thalamic tracts on the left side and succeeded in producing a definite hemihypalgesia without side effects. This diminished the dysesthesia that she experienced on stroking the skin, while the deep diffuse spontaneous pain is still preserved." In further discussion of the patient mention was made of the frequent association of a vegetative state associated with thalamic pain, and the increase of the potentials for sensory disturbances following thalamic injury. Her prognosis was given as most unfavorable, and mention was made of a possible continued vegetative state.

Therefore, recommendation was made that the patient be discharged and subsequent treatment be instituted by X-ray irradiation of the hypothalamus in an area posterior and dorsal to the sella turcica as a possible means of decreasing her hyperalgesia and perhaps a lessening of the vegetative state.

Upon the patient's return home, it was found that she had not retained the benefit noted immediately after the operation, and the neurological institute was again queried. Explanation was given further that such an operation as had been done was often unsuccessful; they again advised X-ray treatment, and in case of failure of that, they stated that they would consider re-operation. On July 3rd the institute, in response to further inquiries about increasing symptomatology in the patient, suggested the possibility of further attempts by new trial medications. They obviously were not interested in another operation and considered the situation as hopeless.

Her family physician then sent her to a general practitioner, who noted upon physical examination a remarkable anomaly not mentioned in all previous examinations—namely, an exact anatomical midline distribution from the scalp to the perineum of the hyperalgesia of the right side of her body and of the normal sensation on the left side, in addition to her vegetative state and the obvious numerous neurological evidences of brain damage. This peculiar anatomical midline demarcation of normal and abnormal sensations he regarded as a hysterical overlay, especially when the patient nodded her

head affirmatively to the effect that the right side of her vagina and rectum were also both continuously painful.

As an outcome of his examination and recommendations the family and the family physician decided to refer the patient to the author for hypnotherapy since, in the 11 months that had already elapsed, there had occurred only a diminution of her hemiparesis and the development of a profoundly vegetative state from which the patient could be aroused only by unusual stimuli, and then only briefly, despite months of continued effort by her family and numerous friends.

The husband hopefully accepted the suggested referral, and the patient was brought to the author on July 14, 1956.

Her husband gave her history; communications sent by the family physician served to give summaries of the patient's four separate hospitalizations—the findings made, the services rendered, and the various respective recommendations suggested. He then proceeded to describe her progressive vegetative decline.

The patient entered the office somewhat unsteadily and haltingly, slumped into the chair, but now and then nodded her head vigorously when her husband stated that she really wished to get well. She presented a most discouraging appearance. Her hair was just beginning to grow out after neurosurgery, the right side of her face drooped, all right-sided movements were awkward, and she gave good evidence by her behavior and manner that she seemed to be suffering severe pain throughout the entire right side of her body. Examination disclosed that gentle touches were less well tolerated than hard slaps or deep pressure on the right side.

It was also noted that she showed marked pain reactions to any stimulus of the right side of her body from the midline of her scalp, down the face and upper chest. Her entire right leg was painful, and she nodded her head toward the right when asked if her vagina and rectum were painful. When asked if she meant only the right side of those parts, she nodded affirmatively. Closing of her eyes during tests or testing the sensation of her back and scalp did not alter the rather remarkable exact anatomical midline division of left-sided normal sensations and the hyperalgesia of the right side. A brief test also disclosed a severe alexia which had not been noted in any of the previous examinations. The history, the appearance, and the obvious physical handicaps, including her aphasia and alexia, left no doubt as to the organic nature of her illness and of actual brain damage, despite the seeming "hysterical" character of her sensory disturbances, which did not allow for the normal interdigitation of sensory nerves from one side of the body to the other.

Inquiry about her clinical course was described by the husband as characterized by brief definite interest on the part of his wife whenever discussion of the possibility of further medical study was mentioned and a hopeful attitude at each clinic, only to be followed by tears, despondency, and apparently profound disappointment each time she returned home unimproved. For several months she had endeavored laboriously to talk to her

husband and children and to participate somewhat in the home life. Sometimes it would take her 15 minutes to say haltingly “I can’t talk” or “it hurts,” referring to the right side of her body. Repeatedly she tried to take an interest in the visits of numerous friends, especially those of her family physician who was also a close family friend, but she seemed to find this impossible. While her paralysis had lessened greatly, she experienced much difficulty ascending or descending stairs or in stepping backward. The patient indicated that in using stairways she had to use the banister because her eyes did not seem to measure the steps correctly, and that stepping backward was a slow, laborious “thinking” process since her feet would lag behind the backward movement of her body, with a fall resulting.

Coldness and increased humidity also increased her physical distress, and her right-sided hyperalgesia as well as increasing the right-sided muscular dysfunction, sometimes severely, depending upon the degrees of cold and the humidity.

The patient’s reaction to her condition at first was one of severe fright and concern. Her first hospitalization was marked by cooperation and an attitude of full confidence in her physicians and the future. The exacerbation of her symptoms that led to her second hospitalization at a nationally famous clinic was accompanied by a reaction of complete hopefulness and certainty. The recommendation there of trial medications and new drugs and the implied hopelessness of her condition resulted in a feeling of despair and, at the same time, a desperate determination to do everything possible to help herself. She did succeed in improving so far as her hemiparesis was concerned, but ascending and descending stairways, her difficulty in stepping backward, the cold winter weather in her home state, and her aphasia and alexia constituted serious obstacles. Codeine and empirin and barbiturates were progressively less effective.

She would struggle vainly and laboriously to talk to her children and husband, but her aphasia gave her so helpless a feeling that she despaired each time. Also, she did not recognize what her alexia really was. She merely felt it to be a peculiar visual impairment of blurring, although objects in general seemed to be clearly outlined.

She made numerous but futile efforts to respond to the almost daily visits of friends, but often found her attention severely distracted from them by surges of pain. There resulted a progressive withdrawal from everything. She would sleep until 10:30 A.M., then arise and take a shower despite the severe pain it caused her. (Her explanation later was that, aside from personal cleanliness, she hoped such a procedure might help her to get accustomed to her constant right-sided hyperesthesia and hyperalgesia.)

She would then eat a combination breakfast and lunch, lie down on the couch, stare at the ceiling, and smoke. At 6:00 P.M. she would arise, eat dinner, return to the couch, stare at the ceiling, smoke and now and then, but with decreasing frequency, try to talk to her husband or to listen to her children, but with less and less success.

Her third hospitalization and the possibility that neurosurgery might be done aroused her intense interest and hope, which turned rapidly into despair. At the fourth hospitalization

she had cooperated with new confidence and enthusiasm but was severely disappointed that only hemihypalgesia was secured. She looked forward to a return to the hospital for a second neurosugical operation and further benefits, but with not too hopeful an attitude. The transiency of the improvement resulted in black despair and a feeling of hopeless frustration, a feeling that had been present for many months but now seemed to dominate her completely. She passively agreed to see the general practitioner recommended by her family physician, but even his discussion of the anatomical midline division of normal and painful sensations as a hopeful evidence of benefit from hypnotherapy did not arouse much active interest. She passively accepted the referral to the author and, upon meeting him, handed him a slip of paper reading, "Help me," very poorly, almost illegibly written.

This special, personally made plea despite the fact that her husband was with her, and the peculiar, seemingly hysterical character of her anatomical midline demarcation of her body sensations, impressed the author most favorably as hopeful indications that the patient would be cooperative in every effort at therapy, and they seemed to represent not hysterical reactions but an extensive somatic overcompensation. Such an explanation was made to her, to her husband, and written in a letter to her family physician. To give her some feeling of faith she was carefully told, with intense emphasis and much elaboration, that such a midline distribution of sensations could very well be interpreted not as hysterical but as an utterly intense compensatory effort by her body to improve and by itself to effect "normal" sensations. This rather specious explanation appeared to give her some faith and hope.

Nevertheless, the problem presented appeared far from hopeful to the author. The first hour's interview exhausted her, and she seemed to have lost interest within 15 minutes, even though her husband did the talking. There was not question of the husband's interest and intense desire to see his wife benefited, but all general understandings indicated that the question of any improvement, if at all possible, would be dependent upon the intensity and persistence of her efforts. Hence, before they left the office, a solemn vow was extracted from the patient to the effect that she would cooperate in every detail with the therapist, and she was warned that "good medicine often tastes bad" and that she would not always enjoy executing therapeutic instructions. She shrugged her shoulders and, after many futile halting attempts, finally managed to say, "I—I do——what——" and when finally asked if she meant that she would do what was asked of her, she nodded her head vigorously.

She was dismissed from the room, which she left rather unsteadily to the alarm of her husband, and certain arrangements were made with him since his business required prolonged frequent absences. These arrangements included the patient's staying with a companion who would serve as an assistant in any way the author demanded. A relative who had accompanied the patient volunteered, and the interview with her led to the conclusion that she would be an ideal person for any therapeutic plan developed.

Three days of intensive thinking of what to do with an obviously brain-damaged patient with definite residuals of a hemiparesis from a hemorrhage within the skull, a severe aphasia, an alexia, a thalamic syndrome for which the patient had undergone thalamic

surgery without recognizable benefit, a history of nearly 11 months' vegetative living in a state of frustration and despair, and an agreed-upon poor prognosis by outstanding neurological clinics led to a decision to investigate experimentally the possibilities of helping the patient by combining hypnosis, hypnotic techniques, the patient's own well-developed pattern of frustration, and the implications of Lashley's work, which, within certain wide limits, demonstrated through experiments of cortical destruction upon rats and monkeys that the loss of learning was largely dependent upon the amount of cortical destruction, rather than the location, and that the learning is carried in the form of neural patterns that in some way preserve their identity in spite of variations in sensory, motor, and cortical elements.

The results the author began achieving led later to a modified adaptation of similar but much less complicated techniques for behavioral retraining under hypnotherapy of a 70-year-old woman previously diagnosed as suffering from a circumscribed irregular arteriosclerotic condition of the brain (Erickson, 1963). In the case now being reported the rationale of the author's decision was that the patient had a well-developed pattern of frustration and despair which, properly employed, could be used constructively as a motivational force in eliciting responses with a strong and probably compelling emotional force and tone leading to actual new learnings of self-expression or possibly to a restoration of some learnings.

The plan devised was complex and involved; sometimes it varied not only from day to day but within the day itself, so that, outside of certain items, the patient never knew what to expect, and even what was done often did not seem to make much sense to her. As a result, the patient was kept in a striving, seeking, frustrated, struggling, and emotional state in which anger, bewilderment, disgust, impatience, and an intense, almost burning desire to take charge and do things in an orderly and sensible manner became overwhelming. (During the writing of this paper the patient was interested in what was being included and pointed out that many times, "I hated you horribly, you made me so furious, and the madder I got, the more I tried.")

Since the problem was clinical in nature and no conventional therapy was known, therapy had to be experimental, but since it was the patient's welfare at stake, there was no way nor attempt at evaluation of the actual usefulness and validity of any single one of the procedures employed. Recognition can only be given to the agreement of competent outstanding clinics in their evaluation of the patient's prognosis as decidedly poor—in fact, hopeless—and the actual eventual outcome of the therapy devised.

Fortunately, the patient's first companion was a highly intelligent, deeply interested, wholly cooperative person with an amazing flow of language and fluency of speech. This was seized upon as the first therapeutic approach, but without acquainting the patient with essential details or purposes.

At the first session the patient was told by the author with painful exactitude and emphasis that she was to extend herself to the very fullest extent of her physical and mental ability to listen carefully to each question the author asked her and to make every

effort to reply, however arduous she found the task to be. She nodded her head vigorously, and she was asked her husband's full name. Before she could complete the first partial efforts to frame his name with her lips, the companion, as previously instructed, replied with great rapidity with his name, age, and birthplace, all of which was gravely recorded by the author as if furnished by the patient.

Equally carefully and slowly, the patient was asked her full name, including her maiden name. Again the companion, while the patient was struggling with her mouth, gave the name, age, street address, etc. On and on this went, the author gravely and earnestly asking the patient questions, recording as if they were the patient's replies each of the companion's answers, some of which were purposely approximations or even wrong. Slowly the patient's early wonderment turned to obvious anger and infuriation, especially at the erroneous answers and misinformation.

At the end of the hour the author remarked casually to the patient, "You're as mad as a wet hen, aren't you?" in response to which the companion verbosely reassured the author that the patient was not in the least angry. The author continued, "And you really don't want to come back either, do you?" Again the companion solicitously reassured the author, while the patient, apparently in an utter fury, with trembling lips, stammered, "I prom—prom—prom—[ised]" and stalked out of the room much more steadily and easily than she had entered.

The next day, as soon as the patient, Anne, was seated, she was asked for her entire history. Immediately, the companion Jane, began a rapid-fire summary of Anne's purported personal history such as date and place of birth, schooling, teachers' names, years of attendance at college, and much family data, many of which were merely approximations or often in actual error. Anne glared at Jane in increasing anger and also at the author, who was hastily making notes and behaving as if it were Anne who was speaking. All of the time Anne's lips and mouth were struggling to reply, to make corrections, and when the hour was concluded by the author's announcement of the hour for the next appointment, Anne stalked out of the office even more steadily than she had before, only to be called back and told gravely that a daily schedule of activities had been arranged for her and that the companion's responsibility was to keep a chart on Anne's cooperativeness. Anne nodded her head vigorously and angrily, turned quickly with a single backward step, and left, still angry. She was called back, and with great intensity, after fixating her gaze rigidly upon the author's face, she was told slowly, repetitiously, that she was to be fully and completely obedient in relation to the schedule. She was then allowed to leave the office, departing at first slowly as if in a trance state and then gradually more briskly. As she turned to leave the office her appearance and manner indicated that she was in a trance. No effort was made to test her for hypnosis. The reasons for this are no more than the author's clinical experience in securing hypnotic responses from subjects without letting them know at first, lest the conscious awareness lead a patient to try to be overhelpful in the therapeutic procedures.

Much later Anne remarked to the author, "I was sent to you for hypnosis, but you never even seemed to try to use hypnosis. When I look back, though, I'm sure you must have

had me in a trance many times when I didn't know it. When I get mad at people, I stay mad—maybe for years. But it was different with you. I'd get mad, really mad, but the next day when I was still mad, something in me made me want to come back.

Maybe that just means you were getting through to my subconscious mind, and that was why. Did you have me in a trance a lot of times?" To this question, since she had not made all the progress the author felt to be possible, his standard evasive reply was given: "I like to help patients, but I often don't try to explain what I'm doing. The answer to your question is, you can guess any way you want to, and either way is all right with me." Such a reply closes the question without answering it, yet leaves the author free to elicit trance states or selected or isolated hypnotic phenomena without the patient's awareness of what is really occurring. Much more readily do patients look upon them as their own conscious intentional effort rather than a passive responsive act elicited by the operator. Leading the patient to "See what I [the patient] can do," is much more effective than letting the patient see what things the therapist can do with or to the patient.

Jane showed Anne a typewritten schedule, but Anne actually could not read it because of her alexia. After many vain struggles by Anne to read it, Jane read it to her several times, but with specified and different errors. Anne listened intently, and her facial expressions indicated that she recognized some of the variously read items and was annoyed. It included bedtime, shower time, meal times, swimming hours, medical appointments, etc., and, most emphatically, the declaration that whatever Jane said or did was to be obeyed scrupulously regardless of what Anne thought, understood, knew, or wanted. There were to be no exceptions of any sort.

This schedule was intended only as another means of stimulating the patient without letting her realize what was happening. Thus, in spite of the clock in full sight and the radio announcing the time as 9:00 o'clock, Jane declared it to be 10:00 P.M. and "bedtime." Anne sputtered inarticulately, and Jane read from the schedule the author's emphatic declaration that Anne was not to dispute or disobey Jane's instructions, all of which were listed on the schedule furnished Jane by the author.

At breakfast time Anne was awakened early and asked if she wanted scrambled eggs, toast, and coffee. Anne nodded her head affirmatively, then noticed that the clock indicated she was being awakened 1½ hours too soon, and pointed at the clock. It was later learned that she recognized the time of day by the position of the hands, not the clock face numerals. Jane cheerfully remarked that it was a lovely morning, and Anne furiously dressed, came angrily into the breakfast room, and was dumbfounded to find oatmeal and a lettuce salad for her, while Jane had fruit, dry cereal and coffee. Immediately after the breakfast, which Anne ate with resentment while Jane cheerfully commented on every topic that came to mind—including the author's absolute order that Anne should always clean up her plate—Jane abjectly apologized for not having told Anne to take her shower before breakfast. Cheerfully and with much light chatter she took Anne back to the bedroom and saw to it that Anne took a shower, completely ignoring all of Anne's efforts to tell Jane by sign language that she had showered, that the shower floor was wet, that the towels proved that she had showered, etc. Jane merely

chatted fluently on a wealth of topics. Jane's sense of humor and zest in following this type of instruction was extremely helpful, and she easily used her own ready ingenuity to execute the author's wishes.

At a later session Anne attempted to communicate effectively by writing a note with her left hand, which she did poorly, and handed it to the author who vainly attempted to read it upside-down and gravely handed it to Jane, who followed suit. Shrugging of shoulders and helpless looks led Anne to say "turn, turn, turn." Obediently the author and Jane turned back toward Anne with further shoulder shrugging. Anne burst into tears and said, "Turn paper round."

This was done, and the request was read "Can she take me diner out?" It was obviously slowly, painfully, and laboriously written.

Immediately consent was given, and Anne unhesitatingly but stumblingly asked, "Breakbreakfast lunchtoo." Ready consent was given, and Anne looked happy and triumphant. Jane had really enjoyed frustrating Anne at every meal by such measures as presenting her with a carrot instead of a banana while Jane cheerfully ate a banana herself. More and more at meals now and then Anne would explosively utter some article of food she wanted, and she was always properly rewarded in an entirely casual matter while Jane chattered endlessly on minor casual topics, always interspersing unimportant minor errors, to Anne's obvious annoyance. Thus a birthday present would be suggested for Anne's oldest child when it was the youngest child's birthday. (Incidentally, Anne was greatly underweight, but she rapidly gained weight in being obedient about cleaning up her plate.)

The request to go out for meals gave new opportunities for Anne's frustration since Jane drove the automobile. It did not take Anne long to discover the need to start to say "Right," meaning "Turn right" a block or so in advance, and shortly to say "Right" at the intersection, since Jane invariably turned the wrong direction or continued straight ahead if not instructed at the proper time.

The menus at the restaurant were another source of instruction and frustration. Since Anne could not read, Jane would order foods that she knew Anne did not like, and always the author inquired if she cleaned up her plate regularly.

Anne attempted to point out to the waitress the items she wished, but Jane stopped that by telling the waitress "Doctor's orders" and reaching for the menu. Shortly Anne began pointing out specific times on the menus, but unless she named it, Jane ordered wrongly. This led shortly to pointing and naming and the getting of some of the foods she wished. Her reading ability soon reached the point where she could read but not always name the item completely. This Jane handled by such a measure as ordering "potato salad" when Anne had pointed to "baked potato" but said only "potato." It was not long before. Anne could say "steak me medium" or otherwise make her wishes clear.

Almost from the beginning the author had taught Anne and Jane the rhyme of "Pease porridge hot, pease porridge cold" and the accompanying hand and arm movements. This game was played regularly with the patient a dozen or two times a day, with Jane reciting the rhyme at first slowly, then with increasing speed. This was done at varying times during the day, sometimes in the middle of a meal or even during a shower bath. Gradually Jane began to make the wrong movements, eliciting corrections from Anne who would spontaneously correct her by saying irritatedly "no, no ," "this this" or "no, this way." Without comment Jane would make the correction, only to make other errors later. Also Jane began reciting the rhyme with variations in tempo. This occasioned considerable annoyance to Anne, who soon began to mouth partially the various words of the rhyme. As Jane noted this, she would make deliberate errors in the words, and frequently Anne would explosively utter the correct words. Often this game was made a part of the therapeutic session with the author so that her progress could be noted and further instructions could be given to Jane about errors to be made.

Direct hypnosis seemed to the author to be impossible; therefore Anne was told impressively within the first two sessions that it would not be employed. (Many months later Anne explained, "You really fooled me when you said `no hypnosis,' that I couldn't be hypnotized. Remember, I asked you before and you just talked and didn't really answer").

Instead, Anne was told in a most painstaking, laborious way, holding her attention in a most rigid, fixed fashion, "As Jane says that rhyme ["Pease Porridge Hot" was not the only one employed; there were many others], listen carefully, hear every syllable. Give it your full attention, notice each sound, all vowels and consonants. Remember each word. Think each word. Remember each word. Think each word. Remember carefully when you were a little girl, when you first learned those rhymes. Where were you sitting or standing? Who taught you? Remember how hard, when you were a little girl, it was to get the words just right. Remember who taught you, where you stood or sat and how, when you learned the onesies and twosies, how happy you were."

The preceding is a brief but representative example of the indirect method of fixating the patient's attention, regressing her in her thinking and remembering to earlier times and situations, and literally inducing through attention-fixation a trance state and possibly some hypnotic age regression through careful use of her actual past history obtained through extensive inquiries of the husband or Jane.

Also, very early in therapy an attempt had been made to capitalize upon infantile utterances such as "goo," "da," "ma" as a measure of teaching the patient to talk. This, however, hurt her feelings and served only to emphasize her infantile helplessness in speaking. This was apparently too threatening a measure, though Anne later told of doing it when alone because she had "promised" to do as told. Also, the author was the only person who seemed to have a genuine hope for her, and she wished not only to please but also to get "even with him for his silly tricks." Thus, a peculiar state of ambivalence, of mixed dislike and liking, existed in the patient, along with a compelling, highly emotional motivation to learn.

Each such session appeared to be followed by improved performance, and Jane's enthusiasm waxed anew each time she made her report preceding each session with Anne.

Rhymes were paraphrased and were fitted into the situation to personalize them to fit Anne's past experience. Thus, mention was made in a session of a certain street address, and at a signal from the author Jane obligingly in a singsong fashion recited "Annie and Willy sitting in a tree, k-i-s-s-i-n-g." The flush on Anne's face disclosed Anne's full remembrance of that specific childhood experience, and the situation was immediately seized upon again to fixate Anne's attention, to emphasize the time, the place, the difficulties in learning childhood rhymes, and the need always to listen to every word and sound. Numerous other little, more-or-less embarrassing experiences of Anne's past were used similarly.

One morning, when Jane had prepared an atrocious breakfast for Anne, Anne pushed Jane aside and, as she walked into the office first, said, "I'm mad——at you——at her too——she helping——can't help get mad—sorry—much sorry."

Anne's facial expression indicated that she was angry, that she regretted it, that she sensed some legitimate purpose on the part of the author and wished for some kind of reassurance.

In reply, with Jane joining in at once, the following rhyme was chanted to her: "Anne is mad and we are glad and we know how to please her; A bottle of wine to make her shine and (husband's name) to squeeze her." Anne's reaction was a joyous response "He's coming, he's coming." By coincidence, her husband was coming into town that weekend, a fact known to the author, and the session was spent planning a pleasant weekend for Anne and her husband with an occasional spontaneous word or phrase from Anne suggesting other possibilities.

She was also complimented on the adequacy of her remarks and speech and told amusedly that however angry or mad she got, the worst was yet to come. Her surprising answer came unhesitatingly, "I'm game." She was beginning to realize her improvement.

Jane was then thoroughly drilled in saying the "Pease Porridge" rhyme in a halting, hesitant, and stuttering fashion.

She learned this in a phenomenally fast manner, and then Anne, who knew nothing of this special measure, was asked to recite with Jane the Pease Porridge rhyme, however hesitantly she had to do it.

Slowly the two began, Anne slowly, while Jane began to increase the tempo and then to stutter the words in a painfully annoying fashion. Anne glanced at the author, was sternly instructed to listen to Jane and to continue the joint recitation. Anne turned to Jane and her lips and face showed the ideomotor, therefore involuntary and uncontrollable, efforts

on Anne's part to correct Jane's stutter. On and on, over and over, Jane continued, with Anne's lips twitching, and finally Anne was haltingly prompting Jane throughout the whole rhyme. This particular session lasted about two hours, and Anne's speech became increasingly better. The same measure was employed with other rhymes, and Anne was obviously pleased and confident though often immensely annoyed.

At the next session Anne made the pitiful plea, "Now Jane is my best——friend——I——like her——much, very much. She—she—she does everything—you tell her. I don't want to hate her. Do—do——do—do—something else."

The author told her sternly, after fixating her attention rigidly by his manner, that he was conducting the therapy, that he would please or displease her as he felt best, but that her obvious improvement warranted a change. She was thereupon instructed to take Jane out to dinner and to put in the order for both of them, asking Jane each item she wished, and doing the ordering and she was assured that Jane would eat it, but she was warned to speak slowly, carefully, or that the situation would be reversed. Several evenings later Jane ate a dinner that was a mess, to Anne's intense merriment and the waitress's bewilderment, since both women were obviously amused and sober (e.g., mustard on lemon meringue pie!).

Interspersed with all of the above therapy was another variety of therapeutic endeavor. This was the beating of time to music, at first to slow music and then to rapid, lilting melodies, although Anne preferred either classical or dance music such as "The Blue Danube." This beating of time followed various patterns: right hand and left hand separately at intervals, then together, then alternately at every other beat; right and left hand separately at intervals, then together, then alternately at every other beat; right and left feet separately at intervals, then together, then left and right feet at alternate beats; left hand and left foot together, then alternate beats for the hand and foot similarly; then left hand and right foot jointly, then separately at alternate beats, then both hands and feet together, separately and alternately and then alternation of left hand, right foot, with right hand, left foot.

Jane was an excellent taskmaster and arbitrarily interrupted meals, showers, television and radio programs at will to ensure "enough practice to satisfy the doctor."

The final step of this measure was to have Anne beat time with the right hand on the left knee, the left hand on the right knee, each time alternating the position of the arms so that first the right arm would be in front of the left, and then vice versa.

As Anne progressed in variously beating time to music, she was instructed to hum. Jane would join in, softly singing out-of-time and off-key, to Anne's annoyance, and then, as Anne began singing the tune, Jane dropped out. In fact, Anne's only protection from Jane being out-of-time or off-key was to hum or sing the tune herself.

Family duties took Jane away, and in her place was put a shy, young, timid girl, extremely sweet and lovable, unwilling to offend and yet obviously afraid not to do exactly as instructed, and easily flustered by sharp criticism.

Anne's reaction was excellent. She liked the girl immediately, adopted at once a protective maternal role, and was constantly springing verbally to the girl's defense at the slightest threat of the author's displeasure directed to the girl.

The excellent progress Anne had made under Jane's care was not only maintained but enhanced by Anne's protective attitude toward the young girl, who was exceedingly conscientious despite her timidity and gentleness, and actually just as competent a taskmaster as was Jane.

More and more improvement occurred; Anne was taught to "relax" as a means of resting from the summer heat of Phoenix, and the girl, an excellent hypnotic subject, would posthypnotically relax with her and in rapport with Anne. Thus, Anne was exposed over and over to the hypnotic situation without ever needing to know she had been hypnotized. She was left no opportunity to wonder and to question and perhaps to doubt her own capacity to improve. Instead she had to attribute her responses and changes not to passive responses to the author and the task he assigned, but to her own efforts explained in part above.

Remembering Jane's conduct at the table, Anne was most careful to spare the young girl the distress Anne felt certain that the girl would experience in obeying the author's instructions if she patted her slice of bread to indicate she wanted the butter and being handed a stalk of celery. Also Anne soon learned that the girl, with obvious distress would reply to a patting of a slice of bread and say haltingly, "But—but—but——" would elicit the verbal response of, "Ask me not but's and I will tell you no lies," or when Anne asked for water by saying "wat—wat—wat" as she lifted her water glass would elicit from the girl a flush of embarrassment and the simple utterance, "What, when, where, and why are parts of speech." Thereby Anne readily realized the competence of Jane's reports, the author's own careful observations during therapeutic sessions, and the thoroughness of the instructions to this girl who aroused so strongly her protective maternal urges. (Incidentally, the young girl, now a mother of several children, and Anne are still the warmest of friends.)

When the author felt that Anne had gained as much as was possible from this protective maternal situation with the girl, a third companion was then secured, after a careful survey of possibilities with Anne's husband concerning friends and relatives who might be willing to serve. The woman selected by the author was oversolicitous, worried, mistrustful, very eager, in fact too earnestly eager to execute whatever instructions she had been given about Anne's daily program, though she did not like them or even understand them. These instructions were carefully limited to what Anne could do either easily or with some little effort. For example, the woman was instructed, "When Anne starts to butter a slice of bread, watch carefully, and when it is half buttered, you butter the other half, or if you see Anne reaching for her glass of water (or coffee cup or glass of

iced tea) nearly empty, you are to jump up and tell Anne, 'You don't need to say a thing, I'll fill it,' or tell Anne to cut her meat or to put lemon in her iced tea, etc." The husband had most emphatically told this companion to obey the author's instructions, however nonsensical they might seem, such as making Anne take a dozen shower baths in a single day or at 2 A.M. or to put the right shoe on the left foot. (This had been done repeatedly by Jane more than once just before bringing Anne to the office.) The first time this happened, Anne angrily extended her feet and pointed at her shoes. The author complimented the appearance of the style of the shoes and the low heels. She shook her head angrily, and the author very rapidly recited the well-known jingle of "goats eat oats, mares eat oats, does eat oats, and little lambs eat ivy."

After a few moments of confusion both women recognized the jingle, but Anne unwittingly went through a mental process of sorting out words and identifying them and differentiating them from the auditory impression given by the rapid utterance.

Later, when Anne was beginning to correct somewhat her alexia, the same measure was employed somewhat differently. Slowly she was taught to recognize the words of similar jingles such as "Nation mice lender ver says knot" (Nay, shun my slender verses not) and then later to be told or to discover the words. This served not only to interest and amuse both women but to effect for Anne possibly a new ordering of her attitude toward words both written and spoken.

This companion's oversolicitude, overeagerness, and overhelpfulness aggravated Anne intensely, and she did every possible thing to prevent being helped. Also, Anne learned to retaliate. Anne herself sought from the author a number of such jingles written out with which to annoy this companion, who seemed to lack much of a sense of humor. Yet, Anne was a sweet personality, and the general relationship between the two women was good. The companion did recognize that in some inexplicable way the author was accomplishing therapy. This companion thus aided greatly in literally compelling more effort on Anne's part in order to escape the oversolicitious aid that served to motivate her to still greater effort. Also this companion could not comprehend what the author was attempting, and was worried and mistrustful of the author. Anne's favorable rapport with the author literally compelled her to demonstrate to this companion that the author's methods, however incomprehensible, were good and most helpful.

However, Anne tired of this companion, and earnestly told the author one day. "She good—do right [obeys author's orders]—not happy job—she have go." This was an exhausting effort at communication because it distressed Anne for two reasons: the discharge of the companion and distress at seeming to oppose the author. Her request was acceded to only after an extensive review over several hours of all the learning she had which had been frustrated by this woman, and then the author made clear to Anne some of his reasons for considering that frustration as desirable, and also why it was not previously explained to her. Additionally, many amused comments were made by the author over the woman's lack of a sense of humor, of Anne's half-resentful, half-amused plaguing of the woman with jingles and in other ways, and he pointed out that the woman always evened the score in some way. Anne did not realize how closely the author

checked the daily course of events with that woman and gave instructions to her to help keep the score even and not to disturb the ties of a distant relationship that existed.

Accordingly, both women were much pleased by the author's termination of her employment, since a new venture in motivating and learning processes seemed in order.

A fourth companion was then secured after intensive questioning of the husband. She was a young girl, obedient but on the whole not too interested or impressed by the various procedures and the monotonous reports and activities at the office. Anne was frequently displeased and disgruntled with her, could find no direct fault with her except her lack of enthusiastic, intelligent interest. She did repeatedly tell the author that she would be glad when she was sufficiently improved to get rid of "that girl with her mind elsewhere." There was no question of where Anne's "mind was." Anne's interest was in her improvement, and she did not like to have anybody, however conscientiously obedient, disinterested. Thus Anne was forced into a position of validating her improvement by being irked, even angered, by her companion's lack of interest and meaningless (to the companion) obedience.

A fifth companion was then secured. This was an older woman, rather absorbed in her own interests, rather "slack about doing things" as Anne complained, and who obviously regarded the author's whole procedure as bizarre, purposeless, and without meaning—even silly and ridiculous. However, care was taken to make sure that she executed her duties, and Anne particularly enjoyed the author's assignment of special bizarre tasks. She also enjoyed the older woman's general dislike of the situation and duties and took particular pride in improving even more extensively just to demonstrate to that woman that the author, whom Anne had now come to like greatly, was correct in his methods and that the companion was wrong (Anne's opinion and emotional reaction to this companion were probably more vital than the author's procedures, which were to intensify Anne's own motivation).

One particular item thought of by Anne at this time was that when she could not say a word, she would "walk around it." The author agreed and pointed out that she could count and stop at the right number when she could not give her son's age. But Anne herself devised the method, when blocked on a word—for example, *butter*—of getting up from the table and elaborately walking around in a tortuous path about the furniture in the room, sitting down and saying, "Pass the yellow stuff there," pointing to it. What Anne did not realize was that, when blocked in saying a word and then walking a tortuous path in and out and around the furniture, she was indirectly and unwittingly adding to her vocabulary and lengthening her sentences. Thus, blocked on saying *butter*, she had, in the procedure she devised, to say to herself mentally, without realizing it, "I must get up and first walk around that chair and then over the end table and past the davenport and open and close the refrigerator door and then go back to the table and say, Please pass that yellow stuff." That this is what actually did occur is not known, nor was any inquiry made. She had suffered brain damage and she was improving by nonconventional methods. Experimentally, it would have been scientific to have inquired of her, but the goal was one of therapy, not of controlled scientific experimentation.

However, a number of normal subjects were deliberately asked to do as Anne and her companion had described as the walking about the room in a random, tortuous path. This done, they were asked to relate the thinking they had done as they did so. Naturally they prefaced their explanation with, “I couldn’t help wondering what your purpose was, but I decided to walk around the coffee table, and then over to the book case, and then around the throw rug and then past the radio.” Anne’s aphasia was a motor asphasia. Presumably her thinking processes were like those of the normal subjects. At all events, she would return to the table with some remark such as, “Pass that yellow stuff there,” instead of limiting her utterances to “Butter, pass,” or “yellow stuff, pass.”

This particular companion was always bored by the sessions in the office, did not try to conceal the fact, and the author took advantage with Anne’s half-resentful half-amused attitude toward the companion, to delight in having them go through the various “exercises” that had been assigned. Particularly did Anne enjoy the author’s discounting of her inability to talk originally by the bald assertion, which the companion resented, that any little baby could say “goo” and “ga” and “da,” and so could Anne. These particular exercises Anne had resented at first. They had been used sparingly in the office, though it was later learned that they had been done secretly by Anne in her apartment. But Anne enjoyed going through them with this companion, even enlarging them from meaningless syllables to baby talk, a measure Anne did deliberately and without prompting to irritate the companion for her criticisms of the author. An excellent, constructive example is, “en—ee—bah—dee,” and this intentionally transformed into “anybody.”

One other step that seemed to the author of importance was the institution of a measure to correct, if possible, the alexia. This the patient was almost irrationally certain could not be corrected despite the considerable progress with menus and jingles, and hence a completely indirect measure was taken. She was furnished pencils and paper and told to sign her name. It was reasoned that, since aphasia involved motor elements and visual word memory and that the alexia was a matter of visual perception, a motor skill might be employed, one that was not related as such to ability to read which is naturally followed or accompanied by reading.

She signed her name in an almost illegible fashion. She could spell her name verbally but could not identify the letters when only one letter at a time was exposed to her. She could recognize her name and her husband’s nickname. She could not recognize her last name or even such a simple word as cat.

She was instructed to take a pencil in each hand and, holding the pencils in the correct writing fashion, simultaneously to write with both hands her own name. She spontaneously noted that her left hand wrote backward and was spontaneously interested in figuring out the probable individual letters in both writings, since the right and left hand writings compared fairly well because of the poor writing caused by the residuals of the hemiparesis of the right arm.

This was one special exercise the author devised which the patient delightedly modified to confound the author while still abiding by instructions. The assignments were her name, those of her family, her birthplace, and then, knowing that she was an ardent baseball fan, she was instructed to write simultaneously with both hands numerous pages filled with the statement that she hoped her favorite team would lose each game. This she did reluctantly—in fact, resentfully. Then one day she entered the office with a broad, triumphant smile with a whole handful of sheets of paper covered with remarkedly improved script. Apprised by Anne's facial expression, the author accepted the sheets most carefully, with only a casual careless look. At first then disappointment, then fury showed in Anne's face, whereupon she demanded imperiously of the author, "You read them." The reply was given that the author had trouble enough reading his own script without attempting someone else's. Since her secret plan was so easily defeated, Anne furiously snatched the papers back and read freely, "I hope the X team wins. I hope other teams lose." in all, she had written and read aloud easily a dozen different statements negating the author's original demand that her team lose, etc.

She was most elated over this, and the author promptly expressed his demand that she write various uncomplimentary things in relation to persons or objects she liked. She took much pleasure in defiance of this by simultaneously writing right- and left-handedly complimentary remarks, and, with less and less halting speech, reading them. She enjoyed this defiance greatly as well as taking much pride in her improved handwriting and ability to identify individual letters and words.

A newspaper was shown her, and she was asked to read an account of her favorite baseball team. She futilely attempted to do so, whereupon the author read it aloud to her, actually paraphrasing it into a most derogatory account. She snatched the paper from the author and haltingly and imperfectly reread the article aloud correctly, half amused, half angry at the author. This measure served to convince her that she could read "if you make me real mad."

There were, of course, numerous other measures essentially variations of those already described, that were employed to prevent boredom or slackness and to keep the patient continuously alert and yet annoyed, frustrated, and at the same time hopeful and pleased by recognizable yet often not immediately realized progress.

By November 1956 she was sent home for two months, returning for further therapy in January and February. She had lost considerable ground, which she attributed to the coldness of her home state. Improvement was rapid and quickly surpassed the previous gains.

She returned home again, and her friends noted no aphasia, although the family physician noted occasional evidences. The alexia persisted, although considerably decreased. Weekly letters from her were demanded, a laborious task often written with many errors. Some of these were arbitrarily sent back with peremptory demands for corrections without the errors being marked. She resented this disdainful handling of her correspondence but invariably found the errors, corrected them, and would append the

statement, “This makes this week’s letter.” (One man-upmanship is a potent therapeutic force.)

Very slowly she began to read short stories to her youngest child. Currently her alexia is far from being corrected, but she can and does read some of the newspaper.

She has been exhibited to a considerable number of physicians as a former patient and has joined the author in challenging them to guess her original diagnosis. Almost all have noted that her right leg is slightly edematous and have offered a diagnosis of thrombophlebitis. On one such occasion she laughingly replied, “You’re right, only you are wrong. Just listen to me try to say that word and you will know.” She then attempted to say “thrombophlebitis” and laughed at the guess of “speech defect,” saying, “No, aphasia,” even adding “from a hemorrhage.”

She still is very slightly awkward from hemiparesis residuals, experiences considerable hypersensitivity and some deep pain of the right side; and cold weather and high humidity greatly increase the deep spontaneous pain and her hemiparesis residuals. She is still taking a minimum dosage of codeine and empirin and an occasional sedative. It was she who persuaded her husband to move to Arizona, but to Tucson, not Phoenix, where the author lives. Thus she is too far away for an emergency call, but she does see the author for occasional visits at irregular intervals of one to four months. For a family physician she was referred to an internist in Tucson, for whom she developed an immediate respect and liking.

She follows a good general daily program except on unusually chilly winter days. That period of the year she is most likely to want to see the author once a month, as “insurance that I am staying all right and it is just the cold that makes things more difficult.” She entertains freely, drives the family car, picnics in the mountains with her family, does the family shopping, but has a housekeeper do routine household tasks.

The specific difficulty in stepping backward had been corrected by having her learn to dance, something she had always enjoyed, and which the first two companions had enjoyed doing with her, the first companion with considerable difficulty, the second with ease, while no trouble was later experienced by the patient in dancing with her husband. Posthypnotic suggestions to the second companion ensured certain awkwardness that Anne helpfully corrected.

Her stair climbing and descending difficulty persists, but the move away from her home state permitted living in a one-level house. However, a climb of two, three, and even four or five steps is easily managed by the measure of carefully noting the number and height of the steps. A larger number necessitates actual assistance.

Cold, if intense, and high humidity, besides increasing the symptoms of her thalamic syndrome and the paralytic residuals, have the peculiar effect of decreasing her sense of taste. This was confirmed by her over- and underseasoning of foods, an item of fact discovered by her family, since she is an excellent cook. At such times she carefully

loads her plate and “cleans it up” so that she will not lose weight because of definite lack of appetite.

DISCUSSION

To discuss the therapy employed and its rationale is difficult. The patient had been rendered suddenly and distressingly helpless at a most happy period of her life but without any loss of her intellectual capacities. The helplessness of her situation, the frequent surges of hope occasioned by trips to nationally famous clinics, the black and hopeless despair that followed, the meaningless, well-intentioned, obviously false and uninformed assurances by all of her friends, associates, and her relatives that “everything is coming along fine,” left her more hopeless and despairing than ever, to say nothing of her actual pain and physical difficulties. She recognized her vegetative state, felt helpless to do anything about it, and found herself facing a completely wretched future for which she could see no remedy nor any way to hope for one.

She knew that the diagnosis of “hysterical reaction of her partial hemiparesis” was wrong because she knew she did have pain explained to her as “thalamic syndrome,” but she did recognize that the general practitioner actually had made a finding he could recognize as new and different from any made by all the other physicians and that he was obviously positive that it signified hope. This had encouraged her briefly, but then all of her hopes had been dashed on previous occasions of optimism.

She had consented to see the author, was again encouraged by his interest in the peculiar midline sensory demarcation and his prompt discovery of her alexia, which he seemed to recognize understandingly, although none of the famous clinics had seemed to pay any attention to it (nor do their reports make any mention of it). Next she was, as she later explained, “fearfully and powerfully” affected by the author’s frank and open statement in her presence that she was a totally hopeless case unless she wanted, *really wanted*, to get well, that every possible opportunity would be given to her, that no effort would be made to spare her feelings at the sacrifice of her welfare, and that the case would be accepted only under an absolute promise of full cooperation despite the fact that therapy would not seem reasonable, nor even sensible nor considerate; that all reasonable, conventional things had been done to no avail for an intelligent adult now reduced to a state bordering on infantile incapacity. Therefore, she would be handled and treated accordingly without regard for her intelligence, her master’s degree, or her social background.

Therapy would be oriented about her helpless condition, and use would be made of every possible pattern of reaction and response that she had retained without regard for banal social conventions, and a demand was made that she give her solemn promise to abide by whatever therapeutic measures the author might propose., It was pointed out simply and emphatically that to date all conventional therapies had failed, that there would be no loss entailed by new measures, and that a therapy devised to meet the actual reality she represented instead of the *lost realities of the past* might conceivably serve a useful purpose. (Later the patient stated that this frank, nonreassuring offer to give help, but a

refusal to promise it, influenced her to take hope and to give and to keep her promise of cooperation despite the anger, frustration, and displeasure the author's methods occasioned. As she explained later, "It didn't make sense most of the time, but I couldn't help noticing that I was doing better. But you did make me just awful mad, and after awhile I discovered it [being angry] helped. Then I didn't mind how mad you got me. But it was awful at first."

Although it cannot be positively stated as factual, one may speculate that the treatment accomplished gains for the patient according to the following utilization of procedures:

1. Her vegetative state was corrected not by sympathetic care and attention nor by patient instruction, but was rendered intolerable by cheerful and obvious stupidity intentionally executed that refuted every intellectual understanding she possessed, and stimulated an actual desire to understand and to learn—but what to learn she did not know. Only a strong and compelling motivation was there, compelling her to seize upon anything offered. It intensified her need to avoid such unmistakably given misunderstandings of her needs, which then led to a frustration state quite different in character from the frustration of incapacity to which she had become so well accustomed. Instead, it was a frustration that compelled her to take action to avoid it by one means or another, and there was no fixed, set, or rigid pathway, nor any opportunity for passive withdrawal, by which she could escape. Each new measure employed by the author placed slightly new and different demands upon her, most of which frustrated her in some new and different way and in a fashion which was intended to lead to effort rather than to a vegetative state. In fact, "cleaning up her plate" when served weird combinations of good, nutritious foods often served to give expression to her innermost emotions of resentment, "which somehow made me feel better."

The emotions accompanying each new demand upon her were something more meaningful than useless despondency and the desperation of the past. There was a desire to retaliate, to do something, to change things, and for varied reasons—anger, amusement, bewilderment, confusion, disgust, etc. There was no one dominant emotional state causing a generalized rejection of things or a withdrawal as had derived from her despair and despondency and depression over her incapacities.

2. General knowledge indicates that verbal learning is based upon a variety of experiential processes. Consider children learning to count. They can learn by rote repetition to count to 10 accurately. Given a good sample of children and various methods employed to teach them to count by verbal instruction and, at the same time, having them touch the instructor's fingers on the nails one by one in proper sequence from one little finger to the next makes the task easier. Hearing, seeing, tactile experience and verbalization combine to facilitate the process of verbal learning. Transfer to a task of counting the fingers without touching them is then easily accomplished. Then the child can be given the task of counting the fingers with the hands turned palms up and counting in sequence from one thumb to the next but without touching the fingers. The task suddenly is more difficult for the child unless he is allowed to touch the fingers. Then the

hands can be held up, the palm of one, the back of the other, facing the child, and he counts readily .without touching the fingers.

Transfer of this learning to the counting of 10 marbles in sequence is then easy. Then place one large marble anywhere, but usually best at the end of a row of marbles, and ask the child to count them visually. The answer too frequently is "nine little marbles and a big one," not the simple reply of 10. Then have that child count the marbles by touching each as he looks at them and counts; the answer is "10, but one is big." Also, how does one learn to read without moving the lips? And the rhythmic person (as the author knows by personal experience and inquiries of similar persons) has intense difficulty in counting the rapid, rhythmical drumming on a table but can count more rapidly and more accurately when a few marbles are dropped from the hand to a tabletop in as rapid but nonrhythmic fashion.

Throughout therapy innumerable items and speculative ideas were kept in mind and revised at each session to fit any immediate changes in the patient's situation and to add new or to arouse old associations to all relearnings and any new learnings.

The Pease Porridge rhyme was ideal for this: it demanded attentiveness, an anticipatory span of attention, coordination of hand, arm, and eye movements, auditory attention, an active motor set and participation; too, presumably, it would arouse some ideomotor and ideosensory and hence involuntary speech movements, possibly, perhaps undoubtedly, including subliminal speech.

Certainly the painful stuttering so deliberately and well-though Laboriously-done by her companion would serve to, and almost be sure to, elicit ideomotor and ideosensory speech experiences. (Consider the overwhelming natural tendency to say words for a stutterer). These would include quite possibly, even probably, subliminal speech and affectively reinforced speech memories, particularly associated motor memories. Also, it would serve to elicit strong self-protection tendencies, a desire to get away from something unpleasing to the self—even as her speech problem was unpleasing to her and it demonstrated that there is an escape from a speech problem—an item of vital general significance.

3. The rhythmic beating of time to music and listening while beating time to lilting songs would lead to ideomotor and ideosensory speech experience, and the peculiar and complex combinations of right- and left-sided beating of time and the constant shifting of the beating pattern from left to right and vice versa were deemed to aid in the development of new alternative neurological pathways of response to auditory stimuli. Additionally, the tendency to hum, to anticipate the next words of the song already heard many times, the tendency to join in the singing, and the frustration by the companion's out-of-time humming and off-key singing appeared to offer a most compelling eagerness and motivation to use her vocal cords out of sheer self-protection, since she did have an excellent ear for music.

4. The patient's markedly underweight state and the authoritative demand that "she clean up her plate" served not only to correct her weight, an item she could sense and appreciate as a visible proof of her improvement, but put her into an eager state of mind of wanting to have her choice of food instead of the nutritious but unwanted selections by her companion. Her appetite, her long-established tastes in food, and her need to protect them served to motivate her desire to speak and also to read the menu so that she could be certain of having her wishes met.

5. The alexia, a distinct problem in itself, is nevertheless related closely to speech. (Watch little children's lips, even those of some adults, as they try to read silently.) Thus, the restaurant menu served the dual purpose of compelling not only speech but reading also. (As reported by Anne later, the first restaurant meal ordered for her, taking advantage of her hopeless speech condition and alexia, aroused not only her anger, but a tremendous desire for doing a turnabout on Jane, something she planned for weeks before the opportunity arose. And such a plan had to be based on actual and inclusive expectations).

Thus the diet frustration, despite her gain in weight, filled her not only with a wealth of mixed emotions but literally forced her into a position anticipative of the correction, but not so recognized, of both the alexia and the aphasia as a means to an end rather than an end in itself.

6. The selection of the first companion was a fortunate act of fate, but it suggested the use of different companions, each to call forth progressively and more assertively the various natural patterns of response that characterized Anne. The first companion by her quickness in seizing upon situations and taking advantage of them while obeying orders forced Anne from a state of frustration and black despair into a state of intense desire to frustrate the companion—hence to do and not to yield hopelessly.

The second companion was picked as a measure of evoking Anne's own deep maternal urges. She missed her family greatly, seized upon the second companion as a substitute, and to the very extent of her ability attempted to do things to prevent the author from rebuking this girl. Also, the girl was a good hypnotic subject and could be given posthypnotic suggestions creative of special situations such as the radiating joy at every success of Anne's and her eyes brimming with tears whenever she mistook Anne's helpless pointing at something instead of naming it and therefore proffering something wrong, which Anne's vigorous negative shake of her head disclosed it not to be wanted. Thus, by virtue of the girl's excellent posthypnotic amnesias, she and Anne would attribute events to situational developments which could not appear in any way to have stemmed from the author's instructions. Also Anne, in her maternalism, would have another type of aversion toward her difficulty, an aversion having its origin in its distress not to her but to someone else. Thus, a set of circumstances could be created in which Anne could take charge spontaneously and not feel that it had been arranged by the author. Anne knew full well that Jane and the author worked hand in hand, but with this girl Anne was inspired to take charge herself. Additionally, the afternoon siesta which posthypnotic suggestion made so easy for the girl served to set an almost irresistible

example leading to "joint relaxation," and Anne delighted in following the example set with the development of an intensely warm interpersonal situation in which Anne was the dominant personality, which was not hitherto the case with Anne's friends during her illness at home nor with Jane. And she is definitely a strong character.

7. The third companion served the significant purpose of compelling Anne to reject emphatically any effort at oversolicitude and to compel a determination to be as self-reliant as possible. This continued unrecognizedly the work initiated by the previous girl and compelled Anne to strengthen it.

8. The fourth girl, by virtue of her feeling of boredom and disinterest, served a most important role of compelling Anne to recognize that much was yet to be done, that much had already been accomplished, and that she herself would have to undertake the responsibility to do all that was requested and even more.

9. The fifth and last companion, absorbed in her own thoughts and troubles, with her tendency to scorn and belittle the author, was actually exceedingly helpful. She powerfully reinforced Anne's assumption of self-responsibility, placed Anne in the position of appraising and recognizing the extent of her improvement, and aroused intense emotional desires to protect the author from criticism of his methods. Thereby Anne unwittingly placed herself in the position of not only justifying and validating the methods, but the forcing of recognition by this companion that the methods were right and that she was continuing to improve.

10. The handwriting exercise in itself was an added special measure of peculiar complexity. Anne knew that she could write only illegibly, and the simultaneous right- and left-handed writing intrigued her curiosity and interest.

At first her left hand wrote more legibly than her right. This pleased her, but although she did not realize it, it also forced her unwittingly into taking a *reading attitude* toward her handwriting. Then having her write derogatory things about her baseball team gave her the golden opportunity to retaliate with much amusement against the author for all the things he had done directly or indirectly against her. By such amused execution of an assigned task, abiding by the essence of the task and yet seemingly defying the author, there was established an easy, comfortable, interpersonal give-and-take relationship between two adults rather than an impersonal physician-invalid relationship. Thus there could be a sense by the patient of sharing significantly and pleasurably in both a joint and a separate accomplishment conducive to her welfare.

As she continued the writing, she realized progressively her capacity to read more and more, and this was assumed by her to be her own spontaneous development. Thus, her faith in herself was greatly strengthened. The impersonally critical treatment of her weekly letters compelled her not only to read while writing them but to read them with searching care *to correct errors*. She enjoyed receiving letters, but cold impersonal criticism of errors noted but not marked in an otherwise friendly newsy letter, coupled with a peremptory demand reminiscent of her original promise to the author, compelled

her not only to read while writing them but to read with searching care to prevent errors. Thus, the return of her letter with a peremptory demand for corrections not indicated for her gave her a golden opportunity to retaliate by searching out the errors and then returning the corrected letter with the triumphant statement that it was the letter for the current week. And one or two occasions in which she missed errors she had made taught her to ensure her triumphant escape from a letter every week because a letter twice returned for correction was accorded no value. Moreover, Anne was strongly competitive, and her need to win was of utmost value in this manner of dealing with her letters. (She now dictates letters by tape recorder—it is more convenient since there are residuals of hemiparesis in her right arm and her alexia is far from corrected so far as writing is concerned.)

11. The recitation of childhood rhymes, little experiences from her childhood, embarrassing or semi-embarrassing incidents, served not only to awaken past memories but to reinforce all associated mechanisms of behavior and learning responses.

12. It is true that the patient's progress might be attributed simply to the increased individual attention she received. However, it is also true that she had received an immense amount of individual attention from numerous relatives, friends, and her family, all of which did not prevent the development of a vegetative state. Also, she received extensive and highly skilled nursing and medical care and attention, all to no avail. But all such care and attention had been based upon concern, sympathy, fear, worry, helpful protective attitudes and a despairing concept of her as helplessly and hopelessly invalided, despite the diminution of her hemiparesis. Such attention was always accompanied by sympathetic and encouraging assurances in the face of obvious and unmistakable disability and therefore was patently false and expressive only of the wishes of others and an unintentional emphasis upon her invalidism. The patient's own retained intellectual capacities permitted her recognition of the falsity of the assurances and the significance of the sympathetic concern as actual expectation of a continuance of her invalidism. As was mentioned early in her medical history, she had a master's degree and possessed excellent intelligence.

The therapeutic attention devised for her and described in this report was of another character entirely. There was no fear, concern, anxiety, or sympathy offered. Instead, there was literally a peremptory demand for cooperation and the exacting of such a promise. Instead of gentleness and sympathetic consideration, there was the annoying assignment of seemingly meaningless tasks and the deliberate devising of situations which would lead to feelings of frustration accompanied by intense emotions of a motivating character rather than of hopeless despair. She was not encouraged to talk, but a situation was created that could lead to involuntary ideomotor efforts of speech and quite possibly to subliminal speech. Frustration was used deliberately to prevent despair by compelling the patient, in self-protection, to strive to secure some satisfaction of ordinary, reasonable, and legitimate desires. For example, being handed a carrot instead of a banana not only infuriated her but tremendously intensified her desire to talk and a need to reject her helplessness so that she might retaliate in kind, as indeed she later did. Yet she had not been asked to talk, which she knew she could not do. Instead, a situation

was created which, through the intensity and welter of her emotions, would impel her to seek some measure or means of meeting her wishes and needs. Neither was she asked to learn to step backward without falling. Instead, her maternal urge to protect the second companion from the author's seeming displeasure about the companion's inability to dance well was used. (A posthypnotic suggestion to the companion ensured a certain awkwardness.) Hence, stepping backward easily and readily was only an incidental and unrecognized part of her emotional relationship to that young girl.

Likewise, the simultaneous writing with her right and left hands, especially of statements offensive to her personal loyalties, could not be recognized by the patient as a form of speech corrective of alexia. To her it was a motor task, repetitious and monotonous, that inspired her to confound and defy the author finally by angrily reading aloud the exact opposite of what he had deliberately misread.

So it was with all of the other individual attentions she received. They were all deliberately and intentionally controlled and directed *toward the evoking of whatever capacities for all kinds of responses which she might have or could develop, without regard for courtesies or social niceties but only for whatever responsive behavior might be conducive to restoration of previous patterns of normal behavior*. However, the nature of her specific reactions was not and could not always be anticipated. *Her welfare* was the governing purpose of the therapy devised—not sympathy, consideration, or even common courtesy. Perhaps the best example to illustrate this was the occasion on which Anne had laboriously, slowly and with apparent distress crossed her legs in an effort to relieve her deep spontaneous pain. When she had completed this difficult task, the author amusedly chanted the old childhood rhyme, "I see London, I see France, I see somebody's underpants." The celerity and ease with which Anne embarrassedly uncrossed her legs with no apparent recognition of painful feelings was a startling revelation both to herself and to her companion. Later Anne recalled this incident by saying haltingly, "member——underpants——move——move leg fast——no hurt."

Numerous other little incidents like this, conducive to strong emotions and automatic responses, unquestionably served to restore and to reinforce normal responsive patterns of behavior and to compel a confident realization of her own recovery of latent capacities of response awaiting adequate stimulation.

13. Hypnosis and hypnotic techniques, usually indirectly and unexpectedly, were frequently employed to arrest and to fixate her attention rigidly upon therapeutic ideas and understandings. By so using hypnosis, her attention was directed and controlled and possible demands for conventionally "sensible" instructions were forestalled. The liking she had developed for the author, the slow but continuing progress which she could see and sense, served with the hypnosis to prevent an intermingling in her conscious daily thinking of conscious doubts, fears, anxieties, and uncertainties with the authors' carefully given helpful ideas. Instead, she became the author's ally, and any questioning doubts were left to the companions.

Even now, seven years later, she feels “different” in the office, and much of her behavior is highly suggestive of a hypnotic state. (For therapeutic reasons no effort is made to test her.) However, this seemingly hypnotic behavior is absent in the waiting room, and she socializes easily and well with the author and others. Another comment in this connection is warranted. About a year ago she met the author at the Tucson airport and took him to her home for some additional therapy. However, she first acted as a hostess, displaying her home and her garden and making inquiries of a purely social character for about an hour. Then when the author remarked, “I believe you have some questions to ask me,” there developed a fixed, rigid attentiveness and a seemingly unwareness of her surroundings similar to that of her behavior in the office.

14. In brief, the therapy developed to meet Anne’s manifold problems may be best summarized as: (a) The devising of measures to negate her passive withdrawal and her vegetative state dominated by a sense of hopeless, helpless frustration; (b) Employment of measures, sometimes directly, sometimes indirectly, capitalizing upon her frustration and despair by employing measures which might conceivably make use of resulting strong emotional drives as a basis of evoking a great variety of response patterns and of motivating learning; (c) Arousal of motivational forces and memories that had played a part in her development from infancy to normal adulthood; and (d) Inducing and compelling an open-mindedness or mental receptiveness to new, inexplicable, curiosity-evoking ideas in settings causing the patient to look forward with hopeful anticipation and not to expend her energies in despondent despair over the past. Always and ever-changing challenging activities of the present and the future occupied her mind, and thus there existed a mental frame of reference conducive to recovery of lost learnings and the development of new learnings, possibly by new and alternative associative neural pathways.

Hypnotically Oriented Psychotherapy in Organic Brain Disease: An Addendum

Milton H. Erickson

Reprinted with permission from *The American Journal of Clinical Hypnosis*, April 1964, 6, 361-362.

In the report presented in the October 1963 issue of this Journal, the fact was not specifically emphasized but is nevertheless obvious that underlying the entire procedure was the utilization of the patient's emotions. Each new measure in some manner elicited emotional reactions, attitudes, and states—sometimes pleasant, but more often of special personal displeasure—and these were employed to intensify and promote her learnings and to stimulate her to greater effort. In some degree, and progressively more and more so, she recognized this through the therapeutic course and endured it willingly, though with frequent reluctance.

At that time thought was given only to the possible effect upon the patient of any sudden catastrophic emotion in relation to family matters of illness and death, which were dealt with adequately as actual probabilities. The patient proved able to cope with this type of stress. However, there was no thought of provision for an overwhelming emotion at a catastrophe of national importance such as she experienced at the announcement of the assassination of President Kennedy. She was an ardent supporter and admirer of the late president, and the announcement of his death had a sudden and detrimental effect upon her. Within a few hours the pain of her thalamic syndrome had increased greatly; she experienced a marked sense of weakness and motor instability; within three days she lost 20 pounds and found the process of eating a laborious task, "I swallow a few bites, then something happens—my appetite—it's gone—I try to eat another bite—I get sick to stomach—try to eat another bite—lose everything. I just eat a bite or two—wait a while—try to eat another—eat all time little bit—mustn't lose weight—but lose fast—awful fast—I'm so weak—so tired—so much pain—no sleep—almost like when I came to you—I'm scared, but still I just want to lie down and give up."

She was brought to see the author after the passage of one week of progressive deterioration. After securing the history, a rapid testing for speech and reading ability was made, which showed no appreciable losses. Her motor ability and ease of walking were definitely impaired. Her right-sided hyperalgesia was severely increased.

Her interest in food, once an item of intense desire and frustration, was gone. Even slight discussion of her previously favorite foods elicited reactions of nausea.

Her previous companions during therapy were indirectly mentioned in a seemingly casual conversation without arousing interest in her, except for the mention of the second companion, the shy timid girl who had stirred her protective maternal emotions. She

otherwise showed marked indifference or an astonishing dislike, but this dislike was found to be related to the course of events in their later lives since the time that they had been her companions. (She and her husband had maintained casual contact with them). More astonishing was the change in her emotional attitude toward her husband and children. Contrary to her usual maternal concern, she showed disinterest in all except her youngest child, but even this was barely more than mild interest. Her attitude toward her husband was cold, unsympathetic, and indifferent, seriously in contrast to the vividly warm affection in which she had held him.

Her husband's spontaneous statement was most informative. It was, "You have just got to do something. I went through this once before, losing hope and faith, just watching her go downhill for almost a year. Except for being able to talk, she's just about where she was when we first brought her to you (1956). 1 can't go through that again, and she can't either. Now do something and do it fast. Make her eat. She tries, but she can't. Maybe you can teach her some way, but do it fast. Make her feel alive and real."

In lieu of any well-formulated or even carefully considered plans, and because the patient was rapidly becoming listless and apathetic, the husband was dismissed, and the author began an exhaustive but vivid discussion of the assassination and its possible immediate meanings and those of historical perspective. The patient's interest was slowly but effectively aroused, at first by a deliberate use of morbidness in the discussion, and then was maintained by as thoughtful and meaningful a discussion as could be offered.

Gradually a shift was made to the youngest child's interest in the same topic, and then to the question of that child's tendency toward overweight and faulty and demanding eating habits, particularly of foods with high carbohydrate content. Then, by extremely cautious indirection, the patient was slowly but intensely inspired (but this was seemingly not noticed by her) to set that child a pattern of table behavioral conduct of such tact and good example as to lead him effectively away from previous indulgence in a large portion of dessert before meat and vegetables and toward a proper approach to kinds and qualities of food. All this was done in a guarded, prolonged, and indirect fashion, and the patient finally left the office more stable physically than she had entered it. Her purposeful attitude and almost peremptory demand that her husband hurry up and get home so that she could prepare dinner for the youngest child was in marked contrast to her behavior upon arrival.

Her husband was promptly and secretly told to be matter-of-fact and noncommittal, to make neither inquiries nor suggestions.

Subsequent information disclosed that the patient had made excellent progress, her thalamic pain had again decreased to its previous low level, and there was little evidence of untoward reaction to the national tragedy. Apparently the appeal to her maternal instinct, so effective in relation to her second companion, again proved a remarkable effective measure of reviving her previous learnings and attitudes.

A month later the patient was again in good condition, although she had not yet gained back all of her weight loss. Her appetite was excellent, but it was noted by her husband that now and then she would seem to have momentary difficulty in swallowing. At such times her husband reported, "Her face gets blank, she seems to forget where she is, doesn't even seem to see us; then she seems to wake up and she doesn't know what just happened to her and keeps on eating. I suppose she just goes into a momentary trance, so none of us say a thing. But she is really doing something about the boy's eating.

"She is not upset anymore, and her pain is greatly reduced. I'd say she's back to where she was except she still lacks 10 pounds, maybe more. She is O.K."

In all, less than four continuous therapeutic hours had been spent with her.

DISCUSSION

The significance of emotional trauma to individual adjustment is universally recognized. But it is noteworthy that in this particular case of the effects of organic brain damage, corrected in large part by new learnings having marked personal emotional components, the adjustment was seriously threatened by a national tragedy with strong personal emotional overtones, even though a death in her immediate family and two other serious family disasters had not caused more than normal grief.

Application of Implications of Lashley's Researches in a Circumscribed Arteriosclerotic Brain Condition

Milton H. Erickson

Reprinted with permission from Perceptual and Motor Skills, 1963, 16, 779-780.

A 70-year-old woman had been repeatedly and separately diagnosed by several different groups of competent neurologists. The findings of each examination were essentially the same. In essence, these were to the effect that the patient was suffering from what appeared to be a peculiar circumscribed irregular arteriosclerotic condition of the brain, resulting in manifestations suggestive of Parkinson's disease which were limited to her face and which affected her speech. Her mental functioning otherwise appeared in no way to be affected. All agreed that no effective medication was known and that the condition was untreatable.

The patient reacted by becoming a dependent, inactive, rather despondent recluse, but after several years of urging by her family, she and her husband consented to attempt again to secure treatment, and she came to the author for hypnotherapy.

Examination of the patient's face disclosed: (a) tremors of the lips; (b) spasmodic, erratic movements of the entire facial musculature; (c) faulty, interrupted verbalizations; (d) athetoidlike movements of her lips and jaw.

Both the husband and his wife were assured of the organic character of her difficulty and of the dubiousness of the effectiveness of therapy except for a possible amelioration of her emotional withdrawal and despondency. They were asked to consider seriously the organic nature of her condition, her age, and the duration of her problem before requesting hypnotherapy. No promise of therapeutic benefits was given and doubt was expressed even concerning emotional benefits, but it was agreed to make an attempt.

Seeking a possible basis and rationale for treatment, the writer called to mind Lashley's research on maze learning in rats, with subsequent relearning after surgical destruction of various areas of the brain, as well as the implications of his research for the utilization of alternate neurological pathways after brain damage. The possible applications of this type of relearning led to the formulation of the following experimental proposal to which they agreed when they returned for a therapeutic session.

The proposal made was that she undergo hypnosis (a) to learn relaxation and (b) to develop motivation to ensure long-continued posthypnotic adherence to all the instructions given her. These were that three times daily, a half-hour each time, she would study her facial image in the mirror and carefully, concentratedly, and repetitiously move her chin up and down and from left to right and back to the midline. Also three

times a day, midtime between her jaw exercises, she was to make deliberately the one-syllable sounds of infantile articulations such as goo, da, etc., also for half-hour periods.

As she progressed in this task, she was to begin talking slowly to her mirror image, carefully observing and endeavoring to make correct facial movements, giving her mirror image such simple instructions as, "Now open [close] your mouth. Now move your chin to the right [left, midline]. Now smile." As soon as she learned this to her satisfaction, she was to explain to her mirror image carefully and systematically the numerous, often complicated, recipes for food which she once had greatly enjoyed preparing.

The patient was most conscientious for some months, during which she developed normal facial movements and speech and returned to her normal home and social activities. This led gradually to a progressive neglect of her daily "exercises," which had been reduced to once a day because of her complete self-confidence. Shortly she experienced a progressive and rather rapid return of her symptomatology, and she was dismayed to learn that she had forgotten her instructions. She returned for further therapy, was given the same instructions again, and within a month regained her normal facial behavior and speech. Since then she has been given "permission to skip exercises" two or three times a week. She now lives and has lived for more than a year a full normal home and social life, much more like that of an energetic 40-year-old woman than one nearly 80. Her recovery has withstood several family tragedies and a progressive slow hearing loss.

Previous to this study a similar experimental reeducative procedure was employed successfully with another patient with brain damage that is yet to be reported. Since then, there has been reported by Slater and Flores in *The American Journal of Clinical Hypnosis* (1963, 5, 248-255) a study of "Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis."

The important question raised by these reports concerns the value of hypnosis in organic disease, the need to recognize the possible potentiating of natural corrective body processes by hypnosis, and the possibility of the establishment of new learning pathways in cases of organic brain disease.

Experimental Hypnotherapy in a Speech Problem: A Case Report

Milton H. Erickson

Reprinted with permission from *The American Journal of Clinical Hypnosis*, 1965, 7, 358-360.

Eight years previously a woman in her mid-sixties had been diagnosed as suffering from "Parkinsonism." She had been dissatisfied with the diagnosis and had sought the opinion of a second and a third neurological clinic. She resigned herself then to the fact that all three clinics independently gave the same diagnosis and offered the same unhappy prognosis. She visited a medical library and read extensively concerning her affliction. This led to a decision to resign herself to her affliction except for one symptom, which she had been told at all three neurological clinics was "atypical" and for which there was no accounting. This symptom was a peculiar harsh, deep-tone, grating, rasping speech, which the author learned to imitate by tensing his neck and thoracic muscles and then tensing his entire abdomen as if he were trying to force air out of his lungs under great pressure while speaking. The patient was noted to behave somewhat similarly but not to the extreme degree to which the author had to resort to match the patient's speech.

She resented her speech difficulty. It was difficult; it tired her; it was unpleasant even to her ear; and she felt that such an atypical symptom could be treated. For the past eight years she had sought all manner of speech therapy to no avail. She finally read about hypnosis and sought therapy from the author.

After securing her history, noting the character of her speech and observing her intensely vigilant attitude and suspicious manner, she was informed that hypnosis was not applicable and that she was not hypnotizable. (This was correct at the time.) Verbally she expressed great regret, but her manner indicated a sense of profound relief, and her entire behavior became much more friendly and cooperative.

She was given a second appointment and a promise that consideration would be given to possible therapeutic measures.

At the next session she was told with impressive emphasis that she might be able to correct her speech if she "concentrated absolutely completely upon a course of relearning" that the author had devised. This was involved and difficult and would require the utmost of mental effort on her part. (The utter confidence and simplicity with which she was so instructed gained her full attention.)

To lay the groundwork for an experimental approach to her problem, all effort at scientific accuracy of problem description or explanation was discarded in favor of securing the patient's full cooperation. Also the author kept in mind his previous

experimental speech therapy with a woman with a localized arteriosclerotic condition of the brain (preceding article in this section). Hence, it was explained that her voice was too deep; that is, her affliction had resulted in the use of muscles deep within her body to give rise to speech. Therefore, it was proposed to create a form of speech that could be located completely above her shoulders. Over and over this explanation was repeated, in varying words and phrases, until her attention was so fixated that she developed a hypnotic trance. (New hope had made her accessible to indirect hypnosis. That such an indirect induction was employed, after her previous relief upon being told that she was not hypnotizable, was entirely legitimate. Her reason for coming to the author was for hypnotherapy despite whatever unfavorable reactions she had toward hypnosis.) Slowly the author went on to explain that this change of speech could be accomplished if she would paste on her bureau, dressing table, and full-length mirrors, typed in large letters, all the nursery rhymes she could discover that she possibly might or could have known in her childhood. Additionally she was told to paste up the alphabet as well. Then she was instructed that she was to listen intently to special explanations and instructions that the author would give her concerning how she was to perform a certain important task. This task was the assignment as a duty for her to *think and read visually* the alphabet forward letter by letter while *saying it backward* letter by letter. Thus she would be in a state of great mental strain. This mental strain would all be above her shoulders, hence her voice would be above her shoulders because all strain and effort would be primarily in her head. Similarly she was to think and read visually the rhyme of "Mary had a little lamb…" forward while repeating it all word by word backward.

She was told to sit or stand in front of her various mirrors from 20 to 30 minutes three times a day, concentrating laboriously on reading visually all the various typed material forward while she laboriously matched each visually read word or letter by softly pronouncing its corresponding place-mate in the end—to—beginning progression of her verbalizations. The reading and the verbalization were to be simultaneous. Thus, as she read the letter A she would pronounce the letter Z, and this she was to practice with such utter intensity that she would hear or see nothing else, unless absolutely important, during each practice session until she developed fluency. In order to avoid the limitations deriving from the trance state that she had unwittingly developed in the office while being given instructions, she was told that she would execute her task with conscious learning as well as with unconscious learning, every day, whether awake, dozing, sleeping, dreaming, hungering, or thirsting. In fact, she would perform her task regularly and happily in whatever mental state would serve to allow her to learn to talk normally in the ordinary course of the day's events and in all personal situations, and that she would do so even if she never in her life—past, present, or future—developed a trance and that under all circumstances whatsoever she would have a full, effective conscious and unconscious awareness of her task. (This all-comprehensive statement, despite the inclusion of the absurd reference to the past, was both reassuring to her and a posthypnotic suggestion reinforced by the emotional comfort suggested.)

She was seen for eight additional one-hour appointments to reinforce her understandings and to give her an opportunity "to practice" in the author's presence to permit further guidance if necessary, but very little was needed. There was no question about the good

quality of her trance states, though no formal induction was employed. Also, she never recognized the fact that she developed a trance each visit. These appointments were spread over a period of two months.

At the end of two months only one or two words out of ten were spoken in the former faulty fashion. The patient was highly elated, and though she moved out of the state, she kept in correspondence with the author to assure him that her problem had diminished to an almost vanishing point, although her other symptoms persisted.

CONCLUDING REMARKS

The therapy devised was patterned with the experimental speech therapy study cited above in mind. It was based in part on the assumption that there could easily be large psychogenic elements in her speech problem. Even if it were completely organic in origin, over the years there had been added a strong emotional reaction to it. Therefore it was reasoned that it would be well to create a learning situation that would bypass the possible psychogenic elements. This could be done with a newly created learning situation that could then be associated with childhood learning situations involving vocalization. By an enforced alteration of a simple visual-vocal reading task, there could be effected a strong divergence of her attention from her speech problem and the learning of vocal reading associated with visual reading as difficult as that combined task had been in her early childhood.

Perhaps this is the explanation of the patient's eventual recovery of better than 90 percent of her disability. This was far beyond all original hopes. However, one experimental instance such as this constitutes proof of nothing more than that many more experimental ventures are warranted in seemingly hopeless problems that are encountered so often in medical practice.

Provocation as a Means of Motivating Recovery from a Cerebrovascular Accident

Milton H. Erickson

Unpublished manuscript, circa 1965.

Karl was in his fifties, an energetic, hard-working man incapable of working for others because of his "German stubbornness," but fully competent to develop and successfully conduct his own business. Karl seldom wasted a moment; he engaged in numerous incidental projects that developed profitably, or else he spent his spare time in extensive reading of a definitely educational character, most of it at a postgraduate level. His personality was that of a "hard-headed stubborn, bullheaded German who insists on having his own way and always works hard enough so that he proves that he's right, even if he has to do things the hardest way first." He was sharp-tempered but essentially kind and most enthusiastically approving of the endeavors of others to work hard, to better themselves, and to achieve. He always had a helping hand to lend any hard-working person who wished to accomplish something, but he would never give more help than was actually needed. Self-reliance, as much as possible, was his guiding personal principle.

Then unexpectedly an unbearable calamity struck Karl, a cerebrovascular accident that paralyzed him and rendered him physically a completely helpless bed patient, capable of understanding but unable even to read or to talk. His communications were limited to head movements, most of them nothing more than an enraged shaking of his head when spoken to or questioned about his needs. As his wife explained, "Karl has always been so capable. He could do just anything, and if he couldn't, he would read up on it and then do it. He just never let himself fail in anything. He is a proud, determined man, and now he is so pitifully helpless. He feels so ashamed because we lost our savings in medical bills and our shop because he couldn't run it and I couldn't. It kills him to have me work. And he is a stubborn, impatient man. He always wants to do things right now and make them perfect. They kept him a whole year at the University on the neurological ward, trying to help him, doing a lot of things. But he was a 'teaching case,' and Karl would go half out of his mind when the medical students would come in and one after another examine him. Then they would hold clinics on him and talk about 'irreparable damage,' 'hopeless prognosis,' and talk about the parts of his brain he had lost because he can't talk and can't read, and Karl would get madder and madder and shake his head so furiously and sweat so they told me they might have to put him on the psychiatric ward. So I took him home, but I can't do much for him except massage and feed and bathe him. He has learned a little use of his one leg and arm, and he can use a cane a little, and if I practically carry him, we can get from one room to another. You saw how he got out of the car and how we came into the office. That's the best he can do." (Watching this activity had been most painful, but it did present good clear evidence of extreme physical

disability somewhat lessened by laborious, awkward, frequently useless efforts at self-help.)

All of this history and further elaborations of the above were taken in the patient's presence. As parts of the history were given, he would nod or shake his head in agreement, or shake his head in anger, perspiring freely as he did so, and he would make grunting and snorting noises expressive of bitter anger and rage when mention was made of the year's thoughtless treatment as a "hopeless teaching case" on the neurological ward (confirmed by the author's personal inquiry while lecturing there).

The purpose in seeing the author, his wife explained, was to have hypnosis employed to reeducate new neural pathways so that he could learn new ways of functioning, new ways of using his arms and legs by employing newly developed neural pathways. A family friend, a physician, had studied an article by the author on the reeducation of a patient with brain damage (Erickson, 1963) and had urged them to consult the author and have the possibilities of reeducation under hypnosis explored for Karl.

A prolonged history was taken from his wife in the patient's presence. The same questions were asked repeatedly in slightly different form. Unnecessary and pointless questions were asked. Throughout this time-consuming procedure the patient was carefully watched, chiefly by peripheral vision so that he would not realize how extensively he was being scrutinized.

Finally the author began asking repeated questions about the patient's willingness to accept help. His wife replied that there would be one serious handicap—namely, however much Karl wanted help, he would insist that it be done his way, "that man can't help bossing everything." She was asked what would happen if "a bigger boss than your husband takes over, then what will he do?" She replied that on a few occasions her husband had had to bow to greater forces than he could muster, that he did so ungraciously and resentfully, but "no matter how mad he gets when he is forced to bend under, he always sees to it that he benefits or profits in some way, and he never holds a grudge very long. He is really too sensible-minded."

The patient listened to all of this, manifesting variously agreement, impatience, resentment, even anger, and boredom. More than once his wife commented, "Look at him now. He is disgusted with all this talk. He wants to get started right now," to which remark Karl vigorously nodded his head in assent.

When the author finally concluded that he had observed the patient long enough and had evoked enough emotional responses and a sufficient number of erratic physical movements expressive of disgust, impatience, and eagerness to permit a somewhat favorable assessment of the therapeutic possibilities, the situation was cautiously outlined to her. Karl listened with mounting impatience, breathing heavily, snorting, grunting, perspiring, and making many minor spasmodic movements with the one leg and arm over which he had gained some slight control. His wife stated in explanation, "Karl wants to start right now. He can't tolerate waiting until tomorrow for another appointment." Karl

nodded a most emphatic assent. His wife added apologetically, “I know Karl, he wants things always his own way, and he wants to start now, so I suppose you will have to cancel the rest of your patients today and work with him.” To this Karl nodded an emphatic affirmation.

The author’s reply was simply that, as a physician, he was in charge of the patient, and any further work would be started the next day. Karl leaned his head back and stiffened his neck and back, whereupon his wife explained, “Karl means he won’t leave your office.”

In reply she was told to bring Karl back at 11:00 A.M. the next morning, and then the author summoned two grown sons and instructed them to pick up Karl, to carry him outside, and to load him into the car gently but most firmly. This they did while his wife wrung her hands, sobbed, and fearfully declared that Karl would never come back. She was reassured, “Not so; that man wants absolute proof that he can be handled, and he will probably make one more test. You say nothing. Disregard everything that Karl tries to communicate to you. Do not be disturbed by anything that occurs. Let Karl seethe in his anger all he wants to. And tomorrow morning at the right time get the car and pull it up to the door on the simple assumption that Karl is going to keep his appointment. Now, dry your tears, straighten your face, talk and act cheerfully.”

Karl refused to eat that evening, refused to be undressed, refused breakfast, snorted, and seemed to be in a continuous rage from the time he left the office. His wife managed to play her part until 10:00 A.M. the next morning, when she asked him if he would keep his 11:00 A.M. appointment. Karl grunted, snorted, and managed to throw his cane on the floor. Then he began perspiring, and he shook his head negatively in a furious fashion. She burst into tears and retreated into the next room. However, at 10:30, when she drove the car up to the front door, she was astounded to see Karl opening the door. In some way he had managed by the use of his cane, chairs, and furniture to work his way from the bedroom to the front door; getting him into the car as well as out of it and into the office had proved easier than she had believed to be possible.

This information was secured while Karl sat alone in the office, apparently raging because the author had left him alone in order to question his wife about the above account of his behavior.

“Well, Karl, I see that you are still mad, but the important thing is that you are here. The rest of the session I will spend merely explaining various things to you, not doing anything, just making clear to you what kind of a job we have to do, how we will have to start at it, and how you are going to take orders and obey them without question whether you like them or not.”

At this point he grunted loudly and shook his head negatively in a violent fashion. “You mean, Karl, that you want to start today?”

Most vigorously he nodded his head affirmatively.

"Well, unless you change your mind rapidly, very rapidly, and decide to let me state how things are to be done, today's interview will be concluded and you can return tomorrow for the explanation I intended to give you today."

For a moment he glared angrily at the author, then resignedly and slowly he nodded assent.

An explanation was then offered that:

1. Hypnosis would be utilized only to the extent considered useful for the varied therapeutic purposes in the author's mind.
2. Hypnosis would definitely be excluded in certain relationships to be determined solely by the author.
3. Prompt and complete obedience would be imperative.
4. All judgmental assessments would be made by the author, and Karl's opinions would be disregarded completely.
5. The author's medical knowledge would govern all matters and Karl's wishes and desires would not be considered.
6. The first evidence of disobedience or hesitation in regard to the author's orders would terminate that particular session.
7. The only information desired from the patient would be the author's own observations and whatever information was requested of his wife.
8. Additional instructions would be formulated as progress was made.

The interview was then terminated by the peremptory measure of stating in a most dictatorial fashion, "Now, get up out of that chair. Stagger your way to the office door and get out of here and get to your car and give your wife's tired arms and back a little rest on the way. Get going!"

Karl's startled look was replaced by a flash of anger, followed by an expression of utterly intense effort as he proceeded, grabbing a chair, then a bookcase to haul himself to the door already opened by the author. Karl's wife came rushing to Karl's assistance but was firmly cautioned to give him only enough help to keep him from falling. Clumsily jerking, twisting, using his wife only to balance himself, Karl made his way to the outside steps, where the author's sons wordlessly picked him up and set him at the bottom of the stairs to make his own way to the car. This he did with increasing clumsiness, and by the time he reached the car he was obviously fatigued. Without a word the author's sons picked him up and placed him in the car, while the author advised his wife to go for a scenic drive so that Karl could rest enough to help her get him out of the car. She was also told that if he grunted to get her attention, she was to tell him, "The doctor says I am to tell you to shut up, so shut up."

TRANCE INDUCTION BY AN AUTHORITARIAN APPROACH

The next day she related that she had to tell him to "shut up only twice" in the 24 hours that had elapsed. She also reported, "He's improving. He let me read the newspaper. He got to the breakfast table alone. He got to the front door alone. I think he wants to tell you about it by having you ask questions so he can nod his head."

Instead, as Karl dragged, jerked, and stumbled with a minimum of help to his seat in the office, he was told peremptorily, "Close your eyes. Lower your head toward your chest. Relax as much as you can. Listen to the clock on my desk ticking. Spend the next 15, 20, 30, 40, 50, or 60 minutes going asleep in a hypnotic sleep. Take the whole hour if you want to. I know you can do it in 15 minutes, but you can take the whole hour and the next hour tomorrow we can spend time doing what could have been done in the 45 minutes left. I'll know when you are in a trance. All you have to do is just go to sleep listening to the clock and waiting for me to talk to you and remaining asleep while I talk to you. Get going!"

Within 15 minutes the tension of his facial muscles had altered in the characteristic hypnotic fashion, his swallowing reflex had disappeared, his respiratory rhythm had greatly changed, and he presented an acceptable appearance of a deep trance. He was told, "Now listen to me. If you are deep asleep, just nod your head gently up and down." Five minutes later he was still perseveratively nodding his head gently in affirmation. This was taken to signify a deep trance, and the noisy dropping of a heavy paperweight on the floor did not elicit a startle reflex or any alteration in his respiratory rhythm.

From here on in the trance state I told him that I reserved the privilege of using invective whenever I pleased, but that his cure was in his hands. He was to walk more and more each day. Within three months he was walking well. On the day he walked 15 miles in the desert areas around the city, he visited me and told me about it in speech that was very clear. He reversed the anger he had had, and used it up in directing his energy into walking and all the other aspects of his rehabilitation. His wife was astonished when she heard him tell me, "I love you as a brother."

R: How often did you see him in that three-month period?

E: Usually when he came to see me he would try to proudly tell me of his progress, but I would make disparaging remarks and accuse him of laziness and giving up too soon. He'd come back a week later and tell me how many more blocks he had walked, but I continued to be unkind in all my remarks, goading him into further effort. When he was in trance, I was very gentle and would only tell him how I was going to act when he was conscious.

R: So when he was in trance, you prepared him for your goading behavior when he was conscious. You were working on his unconscious at one level, preparing him for the motivating provocations you would later hurl at him on the conscious level. How do you explain that?

E: The man really wanted to do things. I carefully told his unconscious that his conscious mind did not yet have the new brain patterns that he needed. So I'm going to keep his conscious mind angry and resentful so he will work while you (his unconscious) help him build up more and more brain patterns. Karl was a tool-and-die maker who had his own factory. He was inventive.

R: So you utilized this inventiveness and the metaphor of making "more brain patterns" because that was particularly apt for a tool-and-die maker who was used to carefully making new "patterns."

E: Yes. Karl did well returning to his factory and supporting his family until he had a much more massive stroke 10 years later. When his wife brought him to me then, she said the stroke was so bad he could not even get mad anymore.

R: He no longer had the motivation to fuel the rehabilitation process?

E: It was unfortunate that when he went back to his factory after his initial recovery, he was even more angry and impatient. He took out some of my assumed anger and impatience and tried to drive his employees too hard. I did not know that at the time.

R: That was an unfortunate side-effect you had not counted on. You helped him live 10 more years of useful life, but his unresolved anger could have been instrumental in that final massive stroke. But we cannot know for sure; in practical clinical work we are usually handicapped by insufficient knowledge.

Do you believe the explanation you gave Karl's unconscious during the trance state was a pseudo-argument, or do you really believe his unconscious was manufacturing new brain patterns? Are new brain patterns being constructed during such rehabilitative efforts?

E: Yes. In my own experience with myself it seems to be a matter of learning to use muscles in a different way. When I was 60, I went for a physical, and the examining neurologist found that I had divided some muscles into halves, some into thirds. One-third of a muscle was realigned to pull against the outer two-thirds of itself. One-half of a muscle was pulled against the other half.

R: You believe that new brain patterns do develop in physical rehabilitation and that these can be manifested by all sorts of readaptations in muscles to recover lost functions. There is greater plasticity in both the central nervous system and our actual musculature than most of us have dared believe. You would definitely encourage more strenuous rehabilitative efforts and greater expectations for recovery?

E: Yes, Karl was told he was a hopeless case, and so was I when I had polio the first time at the age of 17.

Hypnotherapy with a Psychotic

Milton H. Erickson

Unpublished manuscript, circa 1940s

Laskarri had been diagnosed on the psychiatric ward as suffering from schizophrenia of the mixed catatonic-hebephrenic type. He was moderately disturbed in his behavior; several times a day he would shout gibberish apparently at hallucinatory figures and race back and forth and around and about the dormitory beds or scramble frantically under and over them. Or in the dayroom comparable behavior might be manifested in relation to the chairs and tables. Otherwise, he merely mumbled and muttered when questioned, despite the fact that he had a college education. Another item of great interest was his alert, intelligent gaze when not disturbed emotionally. He seemed to be intently studying his fellow patients and the interpersonal relationships between patients and the nursing and medical personnel. Yet when approached directly, his interest seemed to vanish and his gaze became veiled.

INDIRECT TRANCE INDUCTION

Made curious by "this" Laskarri's behavior, the writer approached a passively obedient, rather stuporous patient and maneuvered him into a chair nearby so that Laskarri would have a full view of him. The writer then took a chair slightly to one side so that his primary view was of the stuporous patient but his secondary, somewhat sidelong glance permitted an adequate view of Laskarri. In effecting this seating arrangement the writer spoke earnestly and intensely to the unresponsive stuporous patient, but was well aware of Laskarri's intent observations. The writer then gave the stuporous patient a series of suggestions to induce attentiveness, relaxation, a state of restfulness, a state of attentive sleep, restful sleep during which one might hear, understand, wish to respond, to communicate, to tell things of interest, to need to tell one's thoughts and feelings, to express one's need to ask for help, to do so comfortably even while asleep and without fear.

Previous experimentation with the mildly stuporous patient, who tended to stand about immobile with a vacuous expression in his eyes, had disclosed that he would, if seated in a chair, loll comfortably and seemingly go to sleep. No interpersonal contact had yet been made with him, but he could be used as a suggestive example for Laskarri.

Peripheral vision and sidelong glances soon disclosed that Laskarri, as is common among normal people, was responding to the suggestions he apparently thought were addressed to the subject. Shortly Laskarri gave every appearance of being in a trance, and he manifested catalepsy upon being tested. Slowly the tempo of the hypnotic "sleep" suggestions was decreased, and there was a gradual replacement of them by increasingly urgent suggestions that sometime, somewhere, somehow, courage be found to tell a little,

just a little about what happens when you run, you twist, you turn, you crawl over, crawl under, run, twist, shout, sometime soon, somehow, must some way ... will ... must ... can ... must ... tell what happens when crawl, run, rush, shout, go over, go under.

These suggestions were repeated many times—softly, gently, insistently, urgently—and they were followed with cautious slowness, "... and head will nod, nod, nod, yes ... yes ... yes ... yes ... slowly nod yes ... slowly ... will do ... will do soon."

Shortly Laskarri's head nodded "yes" gently, perseveratively, and further suggestion was offered that he sleep restfully for a while, since he might want to say something that afternoon. The afternoon of that same day the writer slowly made ward rounds, finally seating himself in a chair beside Laskarri and waited patiently. Within 20 minutes Laskarri leaned over slightly and murmured, "Big Joe—you—put Joe asleep—put him asleep—different way."

What Laskarri meant was readily recognized. Some 10 days previously Big Joe, six feet five inches tall and 275 pounds, had become increasingly restless and had announced finally, in the writer's presence, his intention of "singing and yelling for about an hour" and then "smashing the ward and everybody in it." There had been previous such experience with him. Immediately the writer secured a syringe with 15 grains of sterile intravenous solution of sodium amytal and took a seat in front of Big Joe's chair. Suspiciously Big Joe inquired if an intravenous injection was planned. He was told that none was planned, but that if he were to sing and yell for about an hour, his mouth would get dry, but the writer could squeeze a small stream into his mouth without interrupting his singing and yelling and his mouth would not get dry and sore. Big Joe nodded his head agreeably, tipped his head back, and began his bellowing. Little by little the sodium amytal was squirted into Joe's mouth. He swallowed it as he sang and soon lapsed into sleep.

Having thus oriented the writer to his needs, Laskarri's requests now became more personally meaningful. The writer moved his chair closer and Laskarri said, "Sleep—I dream awful dreams—you help." Suggestions of hypnotic sleep were offered, and soon Laskarri was in a trance. He replied to questions of what he should do by answering, "Just let me sleep here in chair—awful dream—hurt—hurt." Taking a chance, I told him, "Sit here in chair, don't move, don't wake up, just don't hurt—just dream awful dream and then tell me."

He seized my wrist, shuddered, perspired, and kept on shuddering and moaning. After some 15 minutes he aroused, stating, "My dream—I had it—I got to keep dreaming until I find out." What it was he had to find out he could not tell. But the next day he could tell the content of the dream, and he begged for further help because he must dream until he found an answer. The content of the dream was that he was being forced, shoved, pulled, yanked, twisted, and thrown through an endless, lightless corridor crowded and filled with bramble bushes, thorny bushes, crucifixion thorns, barbed wire, jagged spikes, long, penetrating slivers of glass, swords, daggers, all manner of painful lacerating, cutting things—a journey that would come to a sudden end with the knowledge that again

he would have to traverse that painful way until he "found it." Though approached many times, Laskarri never had revealed anything verbally to any of the hospital personnel.

Symptom Prescription for Expanding the Psychotic's World View

Milton H. Erickson and Jeffrey Zeig

This paper is a portion of "Symptom Prescription and Ericksonian Principles of Hypnosis and Psychotherapy" presented by Jeffrey Zeig, Ph.D., to the 20th Annual Scientific Meeting of the American Society of Clinical Hypnosis, October 20, 1977, Atlanta, Georgia.

This example is from my initial meeting with Milton Erickson in 1973. It is the first case that Erickson discussed with me in explaining his therapeutic approach. The case description contains some of Erickson's own rationale for his technique, and is quoted directly:

> E: Concerning psychotherapy, most therapists overlook a basic consideration. Man is characterized not only by mobility but by cognition and by emotion, and man defends his intellect emotionally. No two people necessarily have the same ideas, but all people will defend their ideas whether they are psychotically based or culturally based, or nationally based or personally based. When you understand how man really defends his intellectual ideas and how emotional he gets about it, you should realize that the first thing in psychotherapy is not to try to compel him to change his ideation; rather, you go along with it and change it in a gradual fashion and create situations wherein he himself willingly changes his thinking. I think my first real experiment in psychotherapy occurred in 1930. A patient in Worcester State Hospital, in Massachusetts, demanded he be locked in his room, and he spent his time anxiously and fearfully winding string around the bars of the window of the room. He knew his enemies were going to come in and kill him, and the window was the only opening. The thick iron bars seemed to him to be too weak, so he reinforced them with string. I went into the room and helped him reinforce the iron bars with string. In doing so, I discovered that there were cracks in the floor and suggested that those cracks ought to be stuffed with newspaper so that there was no possibility (of his enemies getting him), and then I discovered cracks around the door that should be stuffed with newspaper, and gradually I got him to realize that the room was only one of a number of rooms on the ward, and to accept the attendants as a part of his defense against his enemies; and then the hospital itself as a part of his defense against his enemies; and then the Board of Mental Health of Massachusetts as part, and then the police system—the governor. And then I spread it to adjoining states and finally I made the United States a part of his defense system; this enabled him to dispense with the locked door because he had so many other lines of defense. I didn't try to correct his psychotic idea that his enemies would kill him. I merely pointed out that he had an endless number of defenders. The result was: the patient was able to accept ground privileges and wander around the grounds safely. He ceased his frantic endeavors. He worked in the hospital shops and was much less of a problem.

There is a discernible pattern to Erickson's series of interventions. A comparable pattern can be seen in many of Erickson's cases (cf. Haley, 1973). This pattern can be divided into three major elements, which occur in the following sequence: (1) meeting the patient where the patient is; (2) establishing small modifications that are consistent with, and follow from, the patient's behavior and understandings; and (3) eliciting behaviors and understandings from the patient in a manner that allows the patient to initiate change. These elements are discussed below in relation to the case that Erickson describes.

Initially, Erickson meets the patient where the patient is. In an "anxious and fearful" manner the patient has demanded protection. By assisting the patient in the process of reinforcing the iron bars with string, Erickson provides protection in a manner that is consistent with the patient's frame of reference and indirectly communicates a number of powerful messages. For example, he implicitly establishes a high degree of empathic rapport. The patient is given the opportunity to experimentally understand that Erickson really realizes his dilemma. (The importance of empathy in the psychotherapeutic process has been addressed by researchers [e.g., Carkhuff & Berenson, 1967]. Such researchers have traditionally emphasized the importance of overt and verbal empathic responses on the part of the therapist.) Erickson incorporates a style of using indirection to demonstrate empathic rapport to the patient.

In assisting the patient in reinforcing the bars with string, Erickson enters the metaphor that the patient is living, thereby showing the patient that he respects the patient's integrity and behavior. There is no attempt to interpret the patient's delusion or force him to change his behavior immediately. Rather, Erickson goes along with the patient and thereby begins the therapy on the patient's level of behavior and understanding. If such an initial intervention were made in a sarcastic manner, or from a frame of reference of trying to trick the patient out of his symptom, the positive outcome would be limited. An attitude of empathy and respect on the part of the therapist is crucial to ensure successful change.

After meeting the patient at his level, Erickson makes use of the patient's psychotically based behavior to increase rapport and establish a base for future change. Erickson begins a process of making modifications (finding the cracks in the floor and door) that are in accord with the patient's view of the situation (i.e., the need to protect himself from his enemies). Erickson even seems to immerse the patient more deeply in his psychotic understandings by pointing out the other possible weaknesses in his defense (e.g., the cracks in the floor). However, this maneuver has a paradoxical effect, because by pointing out weaknesses in the patient's attempts to defend himself, Erickson becomes an undeniable defender. He then builds on this small change and subtly aids in the transfer of the protector role to other persons and institutions, until the patient himself can come to the conclusion that he is safe. Moreover, the modifications that Erickson makes seem to have the effect of reframing institutions that the patient may once have feared by emphasizing their protective nature in a manner the patient can account and realize.

The establishment of small modifications by the therapist paves the way for future understandings on the part of the patient that can be oriented in a more positive direction. It can be assumed that most patients have some desire to function in a more effective and enjoyable manner. Through the use of the small modification technique, the patient can avail himself of his desire to function more effectively.

It can further be assumed that the patient has resources in his personal history that can be used to effect change. These resources (past learnings) can be elicited by the therapist in such a way that the patient can avail himself of them. Erickson does not have to teach this patient overtly how to behave in a nonparanoid manner. Rather, he can trust that the patient has years of experience with nonparanoid behavior, and that given the right circumstances, the patient can discover that he can again behave in a nonparanoid manner. In this way the cure is elicited from within the patient.

The initial process of psychotherapy with this patient was based on meeting the patient within his frame of reference and then establishing modifications that the patient could use to establish a new level of functioning. This process is akin to a dance in which one partner begins by synchronizing his steps to the steps of his partner and then (and only then) by beginning to take the initiative and lead.

Overall, the cornerstone of the therapeutic process with this patient is built around the symptom prescriptive approach. In a manner that is basically implicit the patient is encouraged to continue symptomatic behavior until, on the basis of new understandings promoted in part by the modification provided by the therapist, the patient changes his own behavior. While some therapists might engage in such therapeutic practices in a way that is based on trickery or coercion, that is not the case here. Rather, the patient is given the opportunity to recognize and change his behavior to a more constructive and less self-defeating pattern.

Posthypnotic Suggestion for Ejaculatio Praecox

Milton H. Erickson

Unpublished manuscript, circa 1930s.

A 30-year-old unmarried man sought therapy because of premature ejaculation. It had first occurred at his initial sexual experience at the age of 20. His reaction had been most unhappy, and he had then felt that it was punishment for his immorality. He felt damaged and incompetent as a result and rationalized that he would have to correct the condition before he could ever undertake marriage. He became tremendously obsessional on the subject and read everything he could find on sex, searching for some explanation of his specific problem. Additionally, he constantly sought new and different women from every strata of society, age groups, racial groups, and physical types, all to no avail. All efforts had proved futile.

Aside from his obsessional-compulsive search for sexual achievement, he had adjusted satisfactorily. He graduated from college, secured a position as a certified public accountant, and was well regarded by his associates. When asked for a complete description of his behavior in the sexual act, he declared that it was invariably the same regardless of whether his partner were an aging, drunken prostitute or an attractive, charming, well-educated young girl. He never had difficulty in securing and maintaining an erection, even after ejaculation. However, upon an attempt at insertion, ejaculation occurred first. Many times he had disregarded the premature ejaculation and engaged in active coitus, but this gave him neither pleasure nor satisfaction. Rather, he regarded it as an unpleasant effort in a “desperate” desire to achieve sexual competence. Usually he would persist in the intravaginal masturbation until ready for a second ejaculation, whereupon he would invariably and unwillingly but compulsively withdraw. He would then be unable to gain insertion until he had completed the second ejaculation externally. This would always enrage him, and he disliked making the second attempt, but he often felt compelled to do so.

Some months previously he had read this writer’s experimental study on ejaculatio praecox and had promptly attempted to apply it to himself, since he did not want anybody to know about his problem. He had spent much effort in an endeavor to fantasy himself in the experimental therapeutic situation described in that study, but failed completely.

Finally, as a last resort, he sought out the writer. He expressed his willingness for therapy but stipulated that the procedure reported upon in that publication not be used, since he had proved its inefficacy to himself. Nevertheless, he declared his full willingness to leave matters in the writer’s hands completely if that method were not employed. Inquiry promptly disclosed that he regarded hypnosis as permissible; his objection concerned the implantation of an artificial neurosis.

A half-dozen sessions were spent letting him expatiate in endless detail upon his innumerable but futile attempts at intercourse. Throughout each session, in an indirect, unobtrusive, but repetitious fashion, he was induced to emphasize over and over the fact that he never had difficulty in securing and maintaining an erection, until he regarded any inquiry in that direction to be as stupid as repeated inquiries about the number of feet on a biped.

TRANCE INDUCTION WITH POSTHYPNOTIC AMNESIA

With this fact about his competence in relation to tumescence rigidly established in his thinking, he was hypnotized during the next two sessions. He developed a fair trance—not deep, but sufficient for therapeutic purposes in that he experienced considerable posthypnotic amnesia.

In the next therapeutic session, while in a trance state, he was questioned extensively about his current liaisons, which had not been interdicted. It was learned that he was assiduously courting a clandestine prostitute who lived on the second floor of an apartment court, in a suite above the entrance to the court. Access to her apartment was gained by walking the full length of the court, climbing a rear stairway, and then circling back on the balcony. Although the two of them had a full understanding of the intended nature of the relationship, the woman demanded a number of dinner and theater engagements before she fulfilled her "obligations," a not uncommon arrangement in his past experience and one that he liked. The suggestion was offered that, thenceforth, in visiting her, he would develop an erection immediately upon entering the court and maintain it until he left the court, either alone or in her company. This suggestion he accepted readily.

AN ASSOCIATIVE NETWORK OF INTERSPERSED POSTHYPNOTIC SUGGESTIONS FOR NEUROTIC PROBLEMS

Then, for about two hours, a long rambling discussion was offered him. In it were numerous poorly organized comments about his past history, vague speculations about possible meanings and significances of various incidents, and various pleasing but essentially meaningless generalizations. However, systematically and unobtrusively interwoven into that monologue was a whole series of posthypnotic suggestions. These were given at first in random order, with confusing, vague elaborations, until the entire list had been presented. Then they were presented again, over and over, always with much interspersed, seemingly pertinent, but actually irrelevant discussion intended to distract and confuse any attempt at analysis of what was being said. Finally, these posthypnotic suggestions were presented in fairly close succession and in a progressive fashion to build up, without his awareness, certain significant ideas. The possible effectiveness of the suggestions was the primary consideration, not their actual or theoretical validity. These posthypnotic suggestions were as follows:

1. Neurotic ideas and symptoms serve a purpose for the personality.

2. Neurotic manifestations are often seemingly constant but are fundamentally inconstant, since the purposes they serve change as time passes. Circumstances change and personality needs alter.
3. Neurotic symptoms can actually reverse and resolve themselves when the need arises.
4. Correction of neurotic problems can occur as effectively by accidental and coincidental measures as by deliberate effort.
5. No neurotic can really know what will happen to his problem at a given time.
6. Replacement of a neurotic problem can occur by the development of another, and this in itself is beneficial.
7. A specific neurotic symptom such as a premature ejaculation could, without warning, be reversed into a frightening delay of ejaculation, a delay of half an hour to an hour.
8. He would really have something to worry about if that ever happened to him.
9. He really knew how to worry both consciously and *unconsciously*.
10. Such a development would undoubtedly result in a totally unexpected internal ejaculation.
11. Then he would be confronted with the *tremendous problem of accomplished sexuality, which would require constructive utilization*.
12. For the next few days or week or 10 days there would be a growing unrest in him, *presaging an impending change in him*.

The interview was closed with further vague discussion, and he was awakened with instructions to feel excessively tired and to want to go home and to sleep and to do nothing for a while—not even to think—but just to rest comfortably. He was given appointments for the next day, which was Tuesday, and for Wednesday, and Friday. On Tuesday he was seen briefly but not allowed to talk. He was told that he would be given, in return for the briefness of the interview, a very special appointment on Sunday. (The writer was well aware of his Saturday-night regularity.) The Wednesday appointment was similarly handled, with further and extensive emphasis on the Sunday appointment to the effect that he would really have to "give out" for that interview. Friday's interview was also brief, and again emphasis was placed upon the special character of what he would have to relate on Sunday.

All of this maneuvering appeared to bewilder and confuse him. However, on Sunday morning he explained immediately and urgently that, whatever the writer had in mind for the appointment, it would have to be postponed because of certain developments he had experienced. His story was that the three previous brief interviews, or "brush-offs" as he termed them, had made him restless, unhappy, and uncertain. He had been so ill-at-ease after the Friday interview that he sought out his female associate, whom he had been seeing frequently, but with whom he had not yet had sex relations, and suggested a date for dinner and the theater. However, during the evening he had been inattentive to his companion and preoccupied. Recurrently the question "popped into" his mind of whether or not he actually could ejaculate intravaginally. Almost at once the idea would elude his mind, and he would try to remember what he had been thinking. Shortly the idea would

again “pop into” his mind, only to elude him once more. Over and over this occurred, with continued preoccupation on his part throughout the evening.

As he was returning with his companion to her apartment, he developed an erection upon entering the court. This persisted, although he was still so preoccupied with his thoughts, which he could not define to himself, that he did not contemplate sex relations. Nevertheless, upon entering the apartment, his companion manifested such aggressive, amorous behavior that he promptly went to bed with her. Because his preoccupation still persisted, he allowed her to take an aggressive role, and his reaction to insertion was one of sudden fear that he would not be able to have an ejaculation. So absorbing was this fear that “I forgot completely all my past popping off. All I could think of was that I wanted to pop into her, and I was afraid I couldn’t.”

He responded to his fear by active coitus, and “for some unknown reason watching the minute hand on my wristwatch, which I never wear to bed.” As the end of a half-hour approached, he became increasingly excited and, at the same time, more anxious and fearful. Then suddenly, but without noting the time until some 20 minutes later, he experienced a satisfying intravaginal ejaculation. His erection continued, and after a short rest without withdrawal, he engaged in active coitus and had a second satisfying intravaginal ejaculation. Completely satisfied, he waited for detumescence before withdrawal. They slept comfortably and the next day went for an automobile trip. That night there occurred further normal sexual activity.

Upon completing this story, the patient asked if there were any explanation of why he had become normal. Reply was given that neither he nor the writer need explain the normal, that it was infinitely more pleasurable simply to accept the normal unquestioningly as something to which everybody is entitled. (There seemed to be no good reason to permit him to break down his posthypnotic amnesia and thus perhaps vitiate his therapeutic gains.)

His relationship with the woman continued for about three months before they drifted apart. Several other liaisons were formed before he became seriously interested in marriage. At this writing he is engaged to be married, and he and his fiancée are speculating upon building a home. Following his first successful sexual experiences, he was seen professionally a few times, but with no significant communications resulting except his continued adjustment. Thereafter he was seen occasionally on a casual social basis.

Psychotherapy Achieved by a Reversal of the Neurotic Processes in a Case of Ejaculatio Praecox

Milton H. Erickson

Reprinted with permission from *The American Journal of Clinical Hypnosis*,
April, 1973, 15, 217-222.

This author has repeatedly stressed the importance of utilizing patients' symptoms and general patterns of behavior in psychotherapy. Such utilization renders unnecessary any effort to alter or transform symptomatology as a preliminary measure to the reeducation of patients in relation to the crucial problems confronting them in their illness. Such problems cause a distortion of their thinking, feeling, and patterns of living, thereby causing them to seek therapy. By using the patients' own patterns of response and behavior, including those of their actual illness, one may effect therapy more promptly and satisfactorily, with resistance to therapy greatly obviated and acceptance of therapy facilitated. Indeed, it often seems absurd to attempt to reeducate patients when all that may be needed may be a redirection of their endeavors, rather than a change or a correction of their behavior. Particularly so is this true when a patient has a circumscribed type of neurosis.

The fact that a patient has symptoms signifies that some kind of an effort at some psychological or physiological level is being made to alter a troublesome state of being. That patients are disturbed in their behavior means that they are distressed and that they have a desire to put forth effort to alter the situation, but that they do not direct that effort correctly. Furthermore, therapy should be a cooperative venture, the therapist contributing his skills and understandings and the patients contributing their own kind of responsiveness and their own capacities to utilize what can be proffered to aid them. Therapy is never and can never be a simple matter of the patient reacting solely in accord with how the therapist, with his own understanding of what is right and good, might expect the patient to respond. Quite otherwise, the experienced therapist makes clear to patients that responses must be in accord with their own potentialities, even though those potentialities may as yet be unrealized, misused, or misunderstood. What the therapist knows, understands, or believes about a patient is frequently limited in character and often mistaken. What he is willing to let patients discover about themselves and to use effectively is of exceedingly great therapeutic importance. The following experimental hypnotherapeutic handling of a patient's problem of extensive duration will illustrate the above discussion.

THE PROBLEM

A single man, aged 38, had suffered from premature ejaculations since his first attempt at sex relations at the age of 20. This experience had frightened and humiliated him, and it

had deterred him from another attempt for several years. He then sought to resolve his doubts by a visit to a brothel, reasoning that in this way he would experience less humiliation should he again fail. And, as might be expected, he did fail. After a brief period of days he revisited the brothel, this time selecting the least attractive inmate, thinking for some unclear reason that such a choice might be helpful. This endeavor failed also.

He then resorted to casual pick-ups, sometimes on the frank basis of an explanation of his difficulty and an agreement of "no success, no pay." This procedure netted only failure despite assorted varieties of stimulation, some of which led to unpleasant brawls. Liquor was resorted to as a "calming" measure. This too proved to be useless. He finally decided that his problem derived from an overactive conscience. He sought out an eligible, attractive young woman and began a most cautious, chaste courtship. After about six months he realized that he desired to marry the girl, and he asked her for a kiss. A premature ejaculation occurred as he kissed her. Even meeting the girl thereafter resulted in the same unfortunate contretemps.

He discontinued the relationship with that girl and sought out a woman definitely his inferior socially and educationally and "began a slow careful cultivation of her so I could have relations with her. I knew she was promiscuous and that she couldn't understand what I wanted since I only bought her dinners and went to the movies with her until finally I got so sick of her I couldn't stand her. Then I tried it [meaning sex relations]. Same thing! Same old thing."

All of this enraged him and at the same time made him feel so inferior that he sought out prostitutes with great frequency, but always he failed to achieve his goal. The years went by, and he became increasingly fixated upon correcting his problem, first by his own efforts, then by medical and pseudo-medical aids. He was cystoscoped, given prostatic massage and injections of testosterone; he was furnished with various prescriptions, and he purchased many kinds of patent medicines and mechanical aids advertised in magazines. He reacted unfavorably to two physicians who advised him to seek psychiatric aid, insisting that his trouble was organic, noticeably so, and that "it certainly is not in my head."

At long last he learned through the lay press about hypnosis and reached the conclusion that hypnosis was the destined means of putting to an end his obsessive-compulsive search for therapy. He resolved "not to fumble or bumble" in this regard. He rejected lay hypnotists as unquestionably untrained in medical problems and hence charlatans because of the unqualified promises of their advertisements. Physicians consulted too often admitted to ignorance of hypnosis or denounced it, often without actual knowledge, as he realized from his "reading about hypnosis in an encyclopedia and some recent books written by medically trained men."

Eventually he sought out the author, to whom he related his story in extensive, systematic detail. Efforts to get him to abbreviate or to summarize his story were futile. He insisted on doing things his own way. He was unconcerned about how many hours it required to

give an exact, orderly history of his problem. He simply wanted "to be sure that everything is understood ... so that there can't be any failure ... so that I know you know everything."

This rigid, compulsive narration in minute detail of his many failures gave the author adequate time not only to appraise the patient's obsessional-compulsive personality and behavior, but also to speculate upon possible psychotherapeutic measures. The patient's rigidities, his compulsiveness, the fixity with which he had conducted his search for symptomatic relief, the comprehensiveness (according to his understandings) with which he pursued his goal, his perseverance in the face of all difficulties, and the absolute, fixed belief he manifested in the incurableness of his disability all seemed to offer little promise of therapeutic results. When the patient finally concluded the narration of his search for hypnotherapy and his investigation of hypnosis as a possible cure, it became appallingly apparent that the patient was convinced in his own mind that, while hypnosis might readily be an effective cure for others, it was not such for him. He was beyond the pale of hope, and he was merely determined to prove this fact beyond any shadow of doubt. Then he could resignedly abandon his quest for potency and be at peace with himself.

Such was his purpose in seeking out the author and requesting that hypnosis be employed therapeutically upon him. Hypnosis would constitute, so he explained, the utmost, the final superlative method of therapy. Nevertheless, it would fail, since he was at last fully aware of his complete incompetence, and he wished only to put an end to his endless compulsive search for therapy. He felt himself unable to control his obsessive-compulsive searching for an unreachable goal. Once he had tried the ultimate in therapeutic procedures and had encountered failure, then and only then could he resign himself to his fate. This purpose was explained as elaborately as he had given his history.

It was only at this time that the author became fully aware of the nature of the problem confronting him—namely, that the patient had involved himself in an ever-increasing maze of contradictions that was governing his entire personal life.

The realization of this psychological import of the patient's communications suggested an experimental therapeutic approach to the patient's problems that might conceivably be effective. Such an experimental therapeutic approach would of necessity include obsessive-compulsive behavior, actual uncertainty and fear, even a complete expectation of failure. Against this expectation he would be induced to strive desperately and, in so doing, would actually achieve the success so long believed to be impossible. But there would need to be a doubting of the success and many repetitions until he could accept success as a valid reality for him.

This actually simple but seemingly most involved plan of therapy had been roughly formulated by the author by the time the patient had completed his lengthy narrative and argument. During the course of these communications the patient had been induced to disclose a great wealth of details about his present living arrangements, particularly the apartment in which he lived and where he had "tried" with so many women. A useful fact

was that it was reached by following a long outdoor board walkway, a stairway, and a long upstairs balcony walkway; there were other details, many of which were incorporated in the therapeutic plan. The author secretly paid a visit to that series of apartments to be certain of the terrain where the patient had battled so futilely.

THERAPEUTIC PROCEDURE

Therapy was begun by inducing a light trance in the patient and impressing upon him, most tediously, that the "light trance" was a most important measure. Its purpose, he was told repetitiously, was to ensure that he had both a conscious and an unconscious understanding of the fact that a deep hypnotic trance would settle once and for all time whether or not he could ever succeed in sex relations. Two hours of repetition of these general ideas resulted in a deep trance, but no effort was made to give him an awareness of this fact. An amnesia, spontaneous or one indirectly suggested, was desired for therapeutic purposes.

Then, as a posthypnotic suggestion, he was told that he must, absolutely must, get a wristwatch. If at all possible, this wristwatch should have an illuminated dial and illuminated hands. Absolutely imperative was the fact that the watch should have a second hand. The second hand, it was stressed over and over, would be absolutely necessary.

A second posthypnotic suggestion was given that he must, and could, and would thenceforth sleep with a night-light at his bedside so that he could tell time to the very second at any time during the night, since he must, absolutely must, and would wear his wristwatch whenever he should happen to be in bed.

Solemn promises in relation to these demands were secured from the patient with no effort on his part to question the author's reasons for his various insistences.

It was then explained to him that he would continue his "useless inviting of girls to spend the night" with him. To this he also agreed, whereupon it was emphasized that only in this way could he find out what he "really really really would want to learn."

The next posthypnotic suggestion was presented most carefully, in a gentle yet emphatic tone of voice, commanding, without seeming to command, the patient's full attention and his full willingness to be obedient to it. This suggestion was a purportedly soundly based medical explanation of the expectable development, on an organic physiological basis, of his "total problem." This was the fact that his premature ejaculation, by virtue of body changes from aging processes, would be diametrically changed. The explanation was the following posthypnotic suggestion:

> Do you know, can you possibly realize, can you genuinely understand, that medically all things, everything, even the worst of symptoms and conditions, must absolutely come to an end—*but not, but not, 1 must emphasize, not in the way a layman would understand*? Do you realize, do you understand, are you in any way

aware, that your premature ejaculation will end in a failure, that no matter how long your erection lasts, no matter how long and actively you engage in coitus, you will fail to have an ejaculation for 10, for 10 long, for 15 long minutes, for 20, for 25 minutes? Even more? Do you realize how desperately you will strive and strive, how desperately you will watch the minute hand and the second hand of your wristwatch, wondering, just wondering if you will fail, fail, fail to have an ejaculation at 25 minutes, at 25½ at 26, at 26½ minutes? Or will it be at 27½ at 27½ minutes—at 27½ at 27½ minutes? (this last said in tones expressive of deep relief.)

And the next morning you still will not believe, just can't believe, that you won't fail to have an ejaculation, and so you will have to discover again, to discover again, if you really really can have an ejaculation, but it won't be, it can't be, at 27½ minutes, nor even at 28, nor even at 29 minutes. Just the desperate hope will be in your mind that maybe, just maybe, maybe at 33 minutes, or 34, or 35 minutes the ejaculation will come. And at the time, all the time, you will watch desperately the wristwatch and strive so hard lest you fail, fail again, to ejaculate at 27 minutes, and then 33, 34, 35 minutes will seem never, just never, to be coming with an ejaculation.

And now this is what I want you to do. Find one of the girls you are used to. Walk her to your apartment. When you come to the corner at 8th, even as you turn right (all of this was said with the utmost of intensity), try so very hard to keep your mind on the conversation, but notice that you can't help counting one by one the cracks in the sidewalk until you turn into the courtway and step upon the boardwalk. With complete intensity you are to try hard, very hard to keep your mind on the conversation, but keep desperately counting the cracks, the cracks between the boards, the cracks under you (to the unsophisticated, slang often gives opportunities for double meanings), all those cracks all along the way to your apartment until it seems that you will never never never get there, and what a profound relief it will be to enter, to feel comfortable, to be at ease, to give your attention to the girl, and then, and then, to bed, but not the usual—but the answer, the real real real answer, and from the moment you enter [pause] the apartment [pause], your mind will be on your wristwatch, the watch that, as time goes by, can, at long last, bring you the answer.

Quickly now, keep all that I have said in your unconscious mind—locked up, not a syllable, not a word, not a meaning forgotten—to be kept there, used, obeyed fully, completely. You can even forget me, all about me—just obey fully—then you can remember just me and come back and tell me that the wristwatch was right when it read 27½ minutes and when it read 33, 34, and 35.

Arouse now, completely rested and refreshed, understanding in your unconscious mind the completeness of the task to be done." The patient aroused, seemed puzzled, and departed hurriedly.

THE RESULTS

Three days later the patient telephoned to state, "I would like to see you, but I don't need an appointment. I just want to tell you that everything's all right and pay my bill."

He came at the suggested time, stated that the long, detailed account he had given the author of his problem had apparently served as some kind of mental catharsis, that he was fully competent sexually, and that he had proved it to himself repeatedly during the last three nights and mornings. Then, with considerable embarrassment he asked if it were "normal and proper" to prolong coitus "to, let us say, maybe as long as half an hour or more." He was reassured and dismissed, apparently with the hypnotic amnesia still present.

However, from time to time he arranged to meet the author "casually" to exchange a few remarks. About 18 months later he married a woman nine years younger than himself. He announced this to the author over the telephone, and then three months later he asked for an appointment. The reason was simply that he had recovered trance memories. He now had a "full understanding" of what had happened, and he stated his appreciation for the therapy. Actually he had only a general memory of the therapeutic procedure, but he was satisfied with it. He also reminisced about the number of times he "happened to be passing by" when the author came out of his home, and he speculated about the purpose of those meetings.

He explained further that he was certain he had obeyed instructions which had been given to him and that he had been profoundly elated by an ejaculation at 27½ minutes despite intense, despairing fears preceding it. The next morning he had again engaged in coitus with the same distressing fears of failing to ejaculate only to be relieved of those fears by an ejaculation at 33 minutes. He was then convinced that his problem "had reversed itself" and that it had been corrected on some organic basis. He felt a need to retest his "recovery" several times. This had finally given him full confidence in himself, and his self-confidence had never lessened.

He was asked what he thought the author's purpose had been in having him count the cracks in the sidewalk, the boardwalk, etc. His reply was, "I didn't know it then, and I didn't know until you asked me just now. You were having me look at all the useless `cracks' under me before I entered where I succeeded." He flushed as he said this and added, "I think that answer came straight out of my subconscious mind." Seven years have passed, and the marriage has continued successfully.

DISCUSSION

To analyze exactly what was done is rather simple. The patient had told his story, and note had been taken of the patterning of his behavior as was revealed by that story. Then came the problem of devising a therapeutic procedure employing symbolic language expressive of his story. It would need to encompass the same sort of labored, obsessive-compulsive, repetitious behavior, and be provocative of comparable emotions of desperation and defeat, but so organized that the culmination of his behavior would be a

success each time. At no time was he assured of therapy. He was not told that he would have the "real" answer; instead, he was told that the "real real real" answer would become known, and "real real real" is different from "real," as any child knows.

The purpose of the wristwatch was to emphasize, as he had for years, the element of time but in an opposite way. To the wristwatch was attached the same despairing emotion pertaining to time as he had experienced in relation to his long history of failures. The author simply recognized that "failure equals failure," so time (a wristwatch) was equated with failure (failure to ejaculate). "But all things come to an end, even failure." Hence, at the rather peculiar time of 27½ minutes (the oddness of that specified period of time precluded any analysis and compelled rigid attention to the passage of time) the "failure" to ejaculate came to an end. This, of course, could not be a final answer, hence coitus occurred the next morning with the "end" of the "failure" to ejaculate occurring at 33, 34, or 35 minutes. Why such a time specification? Simply to lead him into a situation where he could choose his own time to ejaculate. Remember the patient's guarded inquiry about the duration of intercourse "to, let us say, maybe as long as half an hour or more."

What was the purpose of the hypnotic amnesia? The patient's memories could not be erased, but his immediate awareness's pertaining to his problem needed redirection and reorganization. By "locking his memories" in his unconscious mind there resulted an amnesia of the therapeutic suggestions and a delayed "remembering" of the therapist but nothing more. Thus, he was given a burden of unconsciously remembered ideas which he was to execute in an obsessive-compulsive, desperate endeavor to prevent the failure of the very thing that had constituted the failures of his past. But in the new time setting the "failure" constituted a success that had to be doubted and repeatedly achieved until its successfulness could be accepted as such. This is the kind of thinking which many patients do and which often serves to present an opportunity to turn or to reverse the illogic of their conceptions of themselves into new and better understandings.

Modesty: An Authoritarian Approach Permitting Reconditioning Via Fantasy

Milton H. Erickson

Unpublished manuscript, circa 1950s.

An internist brought his wife in for psychotherapy and stated that he wished to give her history in her presence since he was certain that she would be unable to do so. As a preliminary, he stated that he had used hypnosis in his practice, had found it useful, but had abandoned it for no good reason except that he was more familiar with other methods. He hoped that this would not occasion offense to the author since he was certain his wife would require hypnotherapy.

In summary, the history was that his wife was exceedingly modest despite the fact that she was a registered nurse and that they had been married for 12 years. This modesty consisted of undressing for bed only after he was in bed. Then she would turn off all lights, go into the guest room in the dark, undress, put on pajamas and then a nightgown over them, and come into the bedroom in the dark:

> Our sex life was terrible the first few months, and then she became reasonable. When she finally got pregnant, I had to force her to see an obstetrician, but she wouldn't go until the seventh month. She made him give her ether and he had a hard time. Now our little girl is five years old and she is beginning to notice her mother, and I don't want her to grow up and give her husband the hard time I had.
>
> Then two years ago I demanded a showdown on this nonsense, which was a horrible mistake, only I didn't realize it. I ripped her nightie and pajamas off and made her come to bed and I wish to God I hadn't. She just went into a panic, developed tachycardia, became apneic, then had dyspnea. This was followed by a lot of hysterical behavior, and I had to sedate her. The next day she was phobic and had a compulsion to run out of the house. She would get clear to the end of the backyard before she could get control of herself. This got so bad that she couldn't do her housework. She trembled, she cried, she felt choked up, she had constant difficulty with her breathing, and all my apologies and promises did no good. She just got worse and I took her to your colleague, Dr. X [a psychiatrist]. He hospitalized her for two months for an extensive work-up. I think every consultant in town saw her for everything. She received endocrine therapy, tranquilizers, and everything went well until suggestion of returning home was made. Then there would be more tachycardia, even snycope, and apnea and dyspnea.
>
> Finally he transferred her to the private mental hospital, and he psychoanalyzed her six hours a week for six months. Since this led nowhere, he gave her twelve electric shock treatments. She has been home a year now. At first she was just

> quiet and subdued. She didn't have much to say and kept on coming to bed in the same old way. I felt like hell. During the last three months she has been getting progressively worse. I asked Dr. X what to do, and he offered to do more shock treatment. I don't like the results of that. Then I decided to consult you about hypnosis for her. Will you take her as a patient?

Throughout this narration his wife sat rigidly on her chair, now and then glancing from her husband to the author. She was obviously in a tense emotional state; she appeared badly frightened and embarrassed but in good contact with her surroundings.

Instead of answering her husband, the author asked her if he had given a correct history. She nodded her head and uttered a tremulous "Yes." In reply the author added, "That is, as correct as possible, since he could not really tell how scared you were and still are." To this she nodded her head affirmatively with vigor.

She was immediately asked, "Do you want to be my patient? Remember, I don't use electric shock and I might use hypnosis if I felt it would help."

Resolutely she answered, "Yes, I want help from you—no electric shock, no hormone shots. Just help me stop being so scared." The rest of the interview was spent in securing additional details of history, indirectly confirming the fact that they were in love with each other, and also in endeavoring to encourage the patient to speak more freely. Any questions directed toward the original excessive modesty elicited profound embarrassment and apparently a hysterical apnea. A tentative diagnosis was reached—psychoneurosis of a mixed hysterical and conversion type. This diagnosis satisfied the husband and pleased the patient, who obviously feared, as she later confirmed, that she might be suffering from schizophrenia, a diagnosis that had been more or less broadly hinted at in the private mental hospital.

At the next interview, with her husband in the office with her, she tearfully pleaded that she be hypnotized at once. Both she and her husband stated that he had worked with her as a subject when he was developing his knowledge of techniques, but that, at best, she had been a light trance subject.

TRANCE INDUCTION UTILIZING RHYTHMIC EXPERIENCE

The intensity of her pleas and the pleading look upon her husband's face suggested the possibility of a *corrective emotional experience* (Erickson & Rossi, 1979) by means of hypnosis. As a possible clue to a method of approach she was asked, among other things, if she had ever done any painting or sketching, and had she ever seen or done any ballet dancing. Her answers were puzzled affirmations, and it was also learned that she was a fair pianist. She had also practiced ballet, had done much landscape sketching, and had painted portraits from memory, but all of this was previous to the birth of her child, her one and only pregnancy.

She was then asked to keep in mind some rhythms that she liked and to demonstrate one of them by beating time to it with her upraised hand. At the same time she was to recall her husband's most successful trance induction with her and, as she recalled it, to develop a comparable and then a progressively deeper trance until she could actually hear the music to which she had danced. She responded cooperatively, and shortly gave evidence of a deep trance, beating time with her feet and rocking back and forth in her chair in a childishly pleased and happy fashion.

UTILIZING OBSESSIVE COMPULSIVE PERSONALITY TRENDS FOR FACILITATING HYPNOTIC SUGGESTION

She was asked to listen to the examiner, and she was reminded that she came to receive therapy. Immediately a look of mingled despair and hope came over her face, and she asked, "Can you help me?"

"Only so much as you let me" was the reply, to which was added, "Very slowly I want you, still remaining in a deep trance, to feel completely unable to arouse from the trance, completely unable to do anything except what I tell you, and unable to forget that your husband is here all the time even though you cannot see him. Now there are many things I want you to do, and every one you must do without fail. You won't like to do those things, but such refusal will make it necessary for you to do something you will dislike much more.

"You will have no choice. You came for therapy, you want therapy, you will be offered therapy, and if you try to refuse it and to turn away, you will be confronted with therapy you will like even less. No matter where you turn, you will be confronted on all sides. I suggest that you endure helplessly the therapy that will be presented, because the therapy will be presented as gently as possible. I will only get rough if you try to avoid it." The purpose of this wording was to utilize the possible compulsive and obsessional elements in her behavior and to capitalize upon her long-established method of reacting as if she were behaving under duress.

In elaborating a therapeutic plan for her, the author kept fully in mind the utter childishness of her neurotic behavior that had persisted after a successful pregnancy and despite a reasonably good sexual adjustment. Reflection on the behavior she manifested suggested the possibility of an approach based upon some measure that would be equally childish and absurd, that would relate to her behavior in some contradictory fashion by being uncensored and uninhibited, and would contain in some reverse form the very behavior she had manifested over the years. In this approach there would have to be elements of impulsiveness and compulsive-obsessional coloring of a rather simple, childish, somewhat morbid character. A rather thinly disguised sexual theme seemed appropriate. A fortunate, highly neurotic sexual fantasy of another patient, along with cognizance of the capacity of the average person to be extremely childish, untrammeled, and unguarded in fantasies, finally permitted the formulation of a suitable fantasy for this patient. This could then be imposed upon her in the trance state and play upon the

patient's own patterns of impulsive, and perhaps actually compulsive and obsessional, somewhat morbid patterns that had become habitual for her.

Not much time or effort was required by the author to organize the plan of procedure mentally while he watched the patient continue in the trance and to beat time to the hallucinatory music. Within a relatively brief time, which served to let the patient become more deeply absorbed in the hypnotic state, the author was ready. Accordingly, in a rather authoritative fashion he addressed her:

HALLUCINATORY EXPERIENCE TO REHEARSE THERAPEUTIC CHANGE

> Now listen to me. These are the things you must do. Do them you must, and without fail. Item No. 1 is to open your eyes very slowly, to look at me, to see only me, to know that your husband is here, but you are to be unable to see him. Item No. 2 is that you are to see whatever I tell you to see and to know that you do not know where you are, only that you are sitting somewhere in a room seeing nothing but me, hearing nothing but me.
>
> Now, perform these two tasks. [Slowly her eyes opened, her pupils were widely dilated, and she stared unblinkingly at the author.] Look slowly about you, seeing nothing, hearing nothing except me and an empty room. [Slowly she turned her head from side to side, then looked at the author.]
>
> Item No. 3 is very nice. With your eyes wide open, experience a feeling of profound relaxation and restfulness, a feeling as if you could not move or tense a muscle or breathe faster no matter how hard you tried otherwise. Just feel hopelessly, completely caught in a state of utterly profound, restful relaxation, completely unable to change your restful physical state *no matter how much* you try. And enjoy that feeling of *utterly helpless comfort as long as you can*, because something will happen that will make you mentally want desperately to shake off that warm, comfortable, relaxed feeling. But you will be so completely helpless and comfortable physically and utterly unable to do anything physically, and you will be so horrified mentally that you can derive comfort only from knowing mentally that your husband is here, even though you can't see him. You will be desperately glad he is here. Do you understand?" [She slowly nodded affirmatively with a pleased but puzzled look on her face and a somewhat hesitant character to the nodding of her head.]
>
> Item No. 4 is to see before you a large mirror in which you can see both of us. Right? Now that you see it plainly, I am turning it until you see nothing in it except a small part of a vacant room and a door that looks vaguely familiar in a most peculiar way—just how, you can't imagine. From now on you will breathe deeply, comfortably, with slow regularity, 12 to 14 times a minute, and there is nothing you can do about that except to continue the same slow, deep respiration

comfortably. You cannot move, you cannot close your eyes, you will just look and look and look!

Now you can lean gently, comfortably forward, but that is all, with a peculiar feeling that you know that door, that that door is going to open, that you don't want it to open, but it opens slowly, wide and wider—you can see your face—your own face—Look at that unexpected mischievous smile on your face—on your face—you wonder—you wonder—you have a peculiar impending feeling that something, something, is going to happen, that mischievous smile is getting broader and plainer—Why?—Now you see it fully, you just can't take your eyes off it, you can't close your eyes—you have a grateful feeling for some peculiar reason that the mirror is turned so I can't look in it because—because—look—look behind your face until you see your whole head, and now you can't believe it—you just can't—your neck and shoulders are bare, your chest is uncovered, your body is naked, you are standing there horribly in the nude, you feel so paralyzed in such a peculiar, comfortable way, it's so horrible mentally—you can't stop looking—looking! And watch—watch carefully—you are beginning to dance—ballet dancing—with a wild wild rhythm of joyous abandonment. And what is that? Kicking high, you stand frozen there on one foot, slowly turning your head to see—to see what—somebody is coming—somebody is coming—you can't move—you cannot even stop that mischievous smile—it's frozen—someone coming—sounds like a man. Slowly the mirror turns—slowly the man comes into view—it is your husband and he is laughing—he is clapping his hands—he likes your dance—you become unfrozen and you dance and dance with wilder abandon until you collapse in utter exhaustion and your husband picks you up—for what—the mirror vanishes—just the room is left. Now watch—watch—watch! Watch it all happening just as I described. You can hear my words as each thing happens. See it again—completely.

The patient sat rigidly immobile; only the rapid movement of her eyeballs and the shallow, irregular breathing of an intensely excited person betrayed what she might be visualizing. Suddenly she closed her eyes, slumped in the chair, and smiled, saying as if to herself, "I'm so tired."

She was instructed to rest fully, and that shortly, fully rested, she would sit up and indicate her willingness to listen. Within three minutes she straightened up in the chair, slowly opened her eyes, and stared unblinkingly at the author.

A rapid summary was given of what had occurred, and she was asked if she had watched fully, completely the whole time and had seen everything—everything." With a burning blush she nodded her head to indicate that she had obeyed.

Carefully, in a manner of utter authority, she was told, "You have done well. Now you will repeat that whole task until you have done it five times from beginning to end—see every single part of the entire tableau, collapsing so comfortably at each termination, resting fully for what seems a long time, then going on to the next repetition until all five

times have been completed. You know now that you must do as I say because you can only guess what I would have you see if you tried to refuse to do this task." Slowly she nodded her head and proceeded to behave as if obeying. Thereupon she was told:

> There remains now a most important thing that you are surely going to do, are you not? Item No. 5 is that after you awaken, you will have a total amnesia for all of this that has occurred today in your trance. Today is Tuesday. Then comes Wednesday and Thursday with no memories at all, but you will have some peculiar, indescribable feelings. A feeling that you are going to do something! You will catch a glimpse of yourself in the hall mirror [penciled notes to the husband elicited special items of information], in the sideboard mirror. You will catch a glimpse of a haunting, mischievous smile, but you won't know what it is. You will feel like a tantalized, happy little girl, but horribly thrilled, vaguely certain, awful certain that *something is going to happen that you don't want to happen because you want it to happen*. But what? It will be so tantalizingly close to your mind that you will almost feel that you can reach out and grab it. And every time you walk past a mirror, just as you stop looking in it, you will get a tantalizing half-glimpse of a mischievous smile, only you won't be able to recognize it. You will just half-see it.
>
> And Friday afternoon you won't understand why you are letting your little girl go to visit and stay overnight with the children of your friend. But no sooner has she left than you draw every shade in the house, you draw all the drapes. You will wonder why, why, why!
>
> You will prepare, for no good reason, the best meal you ever cooked, but you will know there is no special occasion, or is there? There will be so many odd, unexpected, intriguing little things happen—interesting, yet they won't seem to have any meaning. The nearer the time comes for your husband's return from the office the more happily alert you will get. And yet such feelings!
>
> You will eat dinner—you will enjoy it—dishwashing will be so easy—so different—never like that before. Why? What next? All evening you will be happily up and down—you will look in every mirror—just a hint of a glimpse. Oh, I just don't know all the simple little ordinary good things you will do, every one of which will seem to bring closer something fascinating, horribly, laughably devilish. You will almost itch all over with wonderment. [The use of the *itch* was entirely fortuitous, an item of fact that will be clarified in its pertinence later.]
>
> Your husband will go to bed early. Subdued, slowly, confused, dully, hopelessly puzzled, you will get ready for bed in the same old way. Something will seem bewilderingly wrong! You will turn on the light. That's not really your regular nightgown—it's ready for the rag bag—those pajamas—an old cast—off pair of your husband's. Appalled, you stand—a sudden impulse—an awful impulse—with a giggle you tear them off—you bound out into the hallway, you snap on the light, you dash into the bedroom, you turn on the light, and you do a rapturous

dance in the nude while your husband sits helplessly in bed and watches until—until—. Now that is what will happen and you won't even guess what happened to make you do all that until I think you should know. And now, you know you will do it, do you not?—She nodded her head slowly, perseveratively.

THE RESULTS

The following Monday her husband reported to the author, "As I listened to you last Tuesday, I didn't know whether to be shocked, horrified, appalled, pleased, or just plain mad at you. What you were saying to her seemed like a crazy, madcap, childish daydream, and I didn't know whether I ought to take my wife home and get another psychiatrist or what. But all of a sudden I kept feeling that I could see that mirror, and that jarred my eyeteeth. Then again I tried to look in it, and when I caught myself straining to do that, I thought I better leave matters in your hands. I knew I couldn't understand.

"We got back home all right. She was silent, sort of wrapped up in her thoughts. One thing that made me sit up and listen was that every time she got near the piano, she'd play a few snatches of dance tunes. Then she played a piece of classical music for me to hear that evening as she often does, and she threw in scattered bits of dance music. It was weird. I'll swear she didn't know it. Bedtime, same old thing. I said nothing, as you indicated to me.

"Wednesday morning, Thursday morning, I saw her ducking her head at first one mirror and then another. I don't know what happened during the day, but I guess she was too busy to have symptoms. She said she was trying to clean out the storeroom, but I noticed a lot of sheet music that we brought from her home when we were first married. And every time she passed the piano, she would ripple her fingers down the keys. And she kept having a puzzled look. There was more classical music, some of her favorites with a lot of little pieces of dance music dropped in. Bedtime, the same.

"Friday noon she called me to tell me Jenny could go to visit with Martha's kids overnight.

"That dinner was wonderful, drapes drawn, candlelight, romantic as could be. She kept turning her head from side to side as if she had heard someone or expected someone. It was funny the way she kept looking at her reflection in the silverware. Half the time she had the most entrancing smile on her face, but every time she looked in a mirror, it would vanish. I could scarcely control myself. She didn't talk much at all. Just silent and absorbed.

"Bedtime, I looked in the guest room. Where she dug them up I don't know, but she hoards dust rags. Then I sneaked into our bedroom. "Everything happened on schedule. It was literally a honeymoon. Saturday morning I called Martha and told her to keep Jenny until Monday morning. Enough said.

“No symptoms, yet. Where do we go from here?”

“Come in tomorrow; that is Tuesday. I’ll take over then.”

The next day, as reported by the husband, the patient rebelled at the proposal that she accompany her husband to the author’s office. However, after much insistent persuasion she came in exceedingly embarrassed. Her opening remark was, “I am too embarrassed even to look at you, Dr. Erickson [she had her hands over her face and was hanging her head]. I know everything that has happened to me. I’ve got a full memory of what you had me do in a trance in the office—if I just close my eyes, I can see the whole thing just as vividly now as I did then. I’m embarrassed. What will you think of me? I remember all the things I did Tuesday, Wednesday, Thursday—and please don’t make me tell about Friday. You would be proud of me, but it’s so embarrassing that I don’t want my husband to tell you even. Will it be all right if I just say I did everything that you or my husband could want? Oh, I mean that differently! Everything that my husband could want and that you would think I should do. Is that enough to tell you, please?”

She was reassured but told, “All I want to know is about your so—called phobia.”

She dropped her hands and declared angrily, “I’m glad you asked about that. I could kill Dr. X for giving me shock treatment for that and psychoanalyzing me and putting me in the hospital for months and giving me all kinds of hormones until I was a human pincushion!”

There was much more said in this same angry vein, but after expressing herself freely, the patient continued: “I just don’t see why I couldn’t have had just simple common-sense therapy. If I ever see that man again, I’ll slap his face! That isn’t very ladylike, and I hope you will forgive me, but my husband is a doctor and I’m a nurse, and we all know that there are some awfully stupid doctors. I even asked him about hypnosis and he sneered and—.” Here she was told, “Quiet down, that’s in the past; now tell me about your phobia.”

Her reply was, “That’s in the past, and 1 just can’t understand how I ever got into that awful way of behaving, but I couldn’t stop. I was just a scared little girl, too scared to think, and I just followed the path of least resistance, only it kept getting worse and worse.

“Then when you made me do those things, it was just like my phobia—compulsive I mean. I felt exactly like a little child—a frightened little child with some kind of a horrible, morbid curiosity. And the more I looked, the more I wanted to, and the stranger it got. Honest, I don’t believe I know half of all the weird things I did Tuesday night and all day Wednesday, Thursday, Friday.” With a flaming-red face she added, “And don’t you dare ask me about Friday night or Saturday or Sunday. You can just be proud of me as a patient. But why did I have to be such a silly child? I wonder if it was because I would think I was too grown up to do something silly like that. I don’t know, but anyway, I’m glad.”

Her husband added a comment here to the effect, “The more I think about it, and the more I think about neurotic behavior in my patients, the more I wonder if they have grown up emotionally. It looks to me, and I’m no expert, as if some of these neurotics ought to be handled on a simple childish level so you can get their understanding.” Here his wife interrupted with, “You can say that for me.”

SUBSEQUENT COURSE

Over a period of five years the patient has been seen at regular intervals for a seasonal dermatitis from which she has suffered since about the age of five years. Previous treatment by various allergists had always been only mildly successful. With the close of certain pollen seasons, her dermatitis would vanish. The season following her hypnotherapy she sought hypnotic relief and amelioration of her skin condition.

This was attempted and proved much more successful than the treatment by the allergist. She reported to him what she had done, and he advised her to continue with the author stating that she was, at least for that season, securing much more relief than he could give her. Hence, each year she reports for her hypnotic symptom relief, and the allergist has continued to check her condition each year because of his curiosity about her much greater response to purely psychological measures than to his method.

Sterility: A Therapeutic Reorientation to Sexual Satisfaction

Milton H. Erickson

Unpublished manuscript, circa 1950s.

A college professor and his wife, happily married for five years and ardently in love, abhorred the thought of children. Both were absorbed in their careers and their home life together. They enjoyed sex relations frequently and intensely and gladly practiced contraception, finding it no significant annoyance. By chance the man was asked by a friend doing research on spermatazoa to furnish a specimen, which he did willingly. Since the friend knew the attitude of the professor and his wife toward children, he did not hesitate to inform the professor that the specimen disclosed complete absence of sperm cells. Interested at once, the professor asked for recheck examinations, and these confirmed the original finding.

Delighted with this news, the professor and his wife abandoned contraceptive measures. During the ensuing year both the professor and his wife became increasingly irritable with each other, and their sexual ardor decreased greatly. Finally they began to discontinue sex relations and to absorb themselves unhappily in their individual activities. Because of continued increasing disharmony for six months, the professor sought psychiatric aid from the writer.

The above history was elicited, and he was then asked to comment on how he felt about the absence of spermatazoa in relationship to himself. He declared that it should be a comforting fact to him, since it did not interfere with him sexually and it removed a possibility that was appalling to both himself and his wife—namely, an undesired pregnancy. Nevertheless, after his first rejoicing, some unrecognized emotional element of a disturbing character had crept into his total affect. What it was, he could not state, but gradually he had begun feeling that he was lacking seriously in those things inherently necessary to himself as a man. Sexual activity had become increasingly meaningless to him, and he had experienced a feeling that his wife was reacting the same way. This had resulted in ever-increasing friction between them until the now-desperate situation had developed.

No attempt was made to discuss his problem with him immediately.
Instead, he was asked to send his wife to the writer for a consultation. She was found to be remarkably frank and clear-thinking. She related a similar story with comparable significances.
At first she had been delighted at the opportunity to discontinue contraception. After some time—at first vaguely and finally with distressing clarity—she had realized that as a sexual mate her husband was biologically deficient—that is, that he could not constitute a biological masculine complement to her biological femininity. It was not that she

wanted to be pregnant; it was merely that she, as a biologically female creature, needed to feel that her mate could, really could, impregnate her. She had reacted to this understanding by trying to force herself to look upon the situation as a fortunate happenstance. Failing in this, she had suppressed her ideas forcibly, with the result that the marital situation had grown increasingly more difficult. Their last sex relations had been more than four months ago and had amounted to no more than a labored, futile, unpleasant effort.

No attempt was made to do anything other than to elicit the above story in clear detail. Then a joint appointment was made for both of them. They entered the office rather diffidently and hopefully, seeming to be eager for help. They were assured most earnestly that their problem could be solved if they could attend to and understand the ideas that would be presented to them. They were told that the discussion about to be offered would be based upon medical concepts that were pragmatically valid and that could reasonably be applied to them. Much of the preliminary discussion would seem irrelevant, they were told, and it would appear to have no relation to their problem. However, it would constitute the essential and elementary foundation upon which they could base an understanding of the correction of their problem.

INDIRECT TRANCE INDUCTION WITH AN ABSORBING ASSOCIATIVE NETWORK

Thereupon, in the most hypnotically persuasive way possible, they were presented with a systematic discussion of concepts of psychosomatic medicine, and numerous case histories and examples were cited to illustrate the effects of psychological forces upon somatic functioning. When they seemed to have sufficient understanding, a long, specious[1] argument was presented that:

> 1. Their joint desire, so strong, to have no children quite possibly could alter their procreative functioning.
> 2. Their use of contraceptive measures quite possibly could reinforce the psychosomatic effect upon their procreative functioning.
> 3. The continuance of contraception kept alive and active the psychosomatic forces militating against procreative power.
> 4. The discovery of a spermatazoa had resulted in the assumption that it signified biological failure with no realization that it was quite possibly a psychosomatic development protective of their actual needs.
> 5. The mere assumption that the a spermatazoa was biological and not psychosomatically functional led to an altered psychological state in them in which an essential element of their lovemaking was absent—namely, the protection of the other from procreation.
> 6. With the discontinuance of contraception, there could result a change in gonadal functioning, but since there was a profound psychological need to avoid procreation, another type of protection would be provided psychosomatically.

7. This new psychosomatic protection against procreation would be the progressive and finally complete loss of sexual interest in each other, a loss that would be distressing and troublesome.
8. Therefore, with these new understandings of possible psychosomatic functioning, it might be well for them to return to their original pattern of happy sex relationships. Thereby, any alteration in gonadal functioning that might have resulted from their abstention and their disturbed emotional states could be corrected by the reestablishment of the original behavioral pattern, and thus they could again have a sense of completeness in their sexual relationships.

They listened to this exposition of ideas[2] with intense interest and seemed to comprehend adequately. A few general questions were answered, and they were given an appointment in another month. At that appointment they reported happily that the understandings they had received had resolved their problem and that their marriage was back on its original status. The professor summarized the entire matter by ruefully commenting upon the human tendency of people, however intelligent, to draw far-reaching conclusions from insufficient data from another field of understanding and to make extensive unwarranted applications of it. Several years later they were still adjusting happily.

---

[1] In this writer's opinion a patient kept awake by severe pain but who sleeps restfully and well as a result of a hypodermic injection of distilled water benefits more than he would from an injection of morphine.

[2]Not only is the writer aware of the superficiality and speciousness of the ideas presented to these patients, but he is also aware of the utter absurdity of their problem and of the appalling readiness with which people can seize upon some inconsequential idea and elaborate it into an overwhelming catastrophe. Furthermore, the writer recognizes that complete awareness of absolute truth is much less available than happy adjustments based upon those partial understandings acceptable to individuals and available and suitable to their own unique limitations.

The Abortion Issue: Facilitating Unconscious Dynamics Permitting Real Choice

Milton H. Erickson

Unpublished manuscript, circa 1950s.

This report concerns a problem of brief duration, decidedly acute in character, and marked by terrified, obsessional, insistent demands. The patients were a young couple in their early twenties. Both were attending college, and they had been engaging in sex relations regularly for nearly a year. They had just discovered that there existed a pregnancy of about two months' duration. Both sets of parents were furious and unforgiving and asserted emphatically that "it better be gotten rid of, or no more college" (one more year of college for each remained). Extreme and unreasoning emphasis had been placed upon the shame entailed for all relatives and friends. The young couple had planned to marry but not until after graduation from college.

The couple were seriously distraught by their situation and by the parental attitudes which had developed to include "no college and no marriage unless you spare us this shame." The father of the young man furnished him sufficient money and advice on where to go to secure the abortion. A friend of the young man, knowing about the situation and aware of the highly disturbed emotional state of the couple, suggested that they see the author and get "tranquilized" before undertaking the risks of an illegal abortion.

Their distress was greatly augmented when the author uncompromisingly discountenanced an abortion. Nor would they listen to the author's suggestions of other, more reasonable possibilities. For two long hours they insistently repeated demands that the author approve the abortion and that he undertake the task himself by using hypnosis to induce physiological activity, thereby making it "legal," and that he prescribe tranquilizing drugs to "calm" both of them. They expressed fear that their overwrought emotional state, in view of the author's lack of cooperation, might cause an abortionist to reject them as too much of a risk, since neither could keep from bursting into hysterical sobs at frequent intervals.

Scattered items of information disclosed that each was an only child, highly protected by rigid and domineering parents, and that they were completely dependent on their parents for everything, including even their opinions in general. They were genuinely in love and were expecting to be married with parental blessings upon being graduated from college. Among the planned wedding presents were a secure position in the firm of the father-in-law-to-be for the young man and a beautiful home from the young man's parents. Now all of this, their entire planned and desired future, was at stake unless they abided by parental commands and secured the abortion.

Two full hours of desperate endeavor failed to make the slightest impression upon their insistent, hysterical, highly obsessional, repetitive demands.

TRANCE INDUCTION BY UTILIZING OBSESSIVE BEHAVIOR, QUESTIONS, NOT KNOWING, AND A REVERSE SET OF SURPRISING IDEAS

Finally the author decided to capitalize upon the obsessional, fearful behavior they both manifested by using that very behavior itself. As everybody knows, it is impossible to hold a stopwatch to time one's self and to avoid thinking about an elephant for one whole minute. This simple childish challenge seemed to present a method of dealing effectively with the problem they presented. Accordingly, the author emphatically demanded:

> All right, all right, quiet now, quiet, if you want the help you ask. Be quiet and let me tell you how to ensure getting the abortion you are desperately trying to prove to me that you want. You have told me you want the abortion. You have told me that there is no other choice. You have told me that, regardless of everything, you are going to go ahead with the abortion. You declare most emphatically and resolutely that nothing can stop you. *Now let me warn you about one thing that can stop you, that will surely stop you, against which you will be totally helpless if you are not warned about it in advance. Quiet now! Listen attentively because you need to know this if you really want the abortion, if you really intend to get the abortion*. Now listen quietly and attentively. Are you listening? Both nodded their heads silently, expectantly.
>
> You do not know an important thing, a vitally important thing. That essential information is this: You do not know whether that baby is a boy or a girl. You do not see, cannot see, the vital connection between that question and the abortion you have told me that you want. *Yet that question will prevent you from getting the abortion since you don't know the answer*. Your personalities, your psychological makeups make that question important. You do not know why, but who expects you to know? Let me explain! If that baby were going to be kept by you, you, not knowing if it were a boy or a girl, would have to think of a name for it that would fit either sex, such as Pat, which could be either Patrick or Patricia, or Frances for a girl or Francis for a boy. *Now that is the very thing you must avoid at all costs*. Under no circumstances, not even once, after you leave this office, are you to think of a possible name for that baby, a name that would fit either sex. *To do so and to keep on doing so would compel you psychologically to keep the baby*, not to get an abortion. Hence, under no circumstances are you to dare to think of a name for that baby. Please, please don't, because then you won't get an abortion. Every time you think of a name, that thinking will definitely deter you from getting an abortion. You will be forced into taking the money you have and seeing a justice of the peace and getting married. You want an abortion, and you can't have it if you think of a name, so don't, just don't don't don't think of a name, any name for the baby *after you leave this office, because if you do, you will keep it, so don't don't don't think of a name, any name*. Now without another

word, n*ot one word, not a single word, especially not a baby's name*, leave this office at once.

Thereupon the author took them by hand and led them quickly to the door to hasten their departure.

Several days later they returned, smiling in an abashed fashion, stating, "After we got married *because we just couldn't help thinking of dozens of names, and every name made the baby more precious to us*, we realized that all you did was bring us to our senses before we did something awful foolish and awful wrong. We had just lost our heads, and our parents didn't help either—that's why we acted like such awful fools in your office."

Inquiry disclosed that both sets of parents accepted the elopement instead of an abortion with a profound sense of relief. The original plans for setting-up the young couple were carried out when the husband was graduated.

The young mother had to delay her graduation for some time. Then the grandmothers alternately baby-sat so that the young mother could complete her college work. At the present time little Leslie has several younger siblings.

From the very beginning of the interview with this distraught couple the extreme obsessional character of their behavior, thought, and emotions was most marked. They seemed, as persons, to be basically sound yet caught in a situation they could not handle. Hypnosis was obviously not a suitable procedure, but it was realized, as observation of them continued, that a hypnotic technique of suggestion, seemingly worded to favor undesirable results, could effect positive results and that a specious psychological contingency could be so emphatically suggested to them that their own hysterical obsessional behavior would make it effective in securing a desirable end result. The emphatic presentation of the problem of not thinking of a name befitting either sex *outside of the office*, only incidentally mentioning marriage by a justice of the peace without actually suggesting that they resort to it, precluded any tendency for them to rebel because they had been "told what to do." This created a favorable climate for their voluntary marriage by a justice of the peace, since they were not recognizably so instructed. Fundamental to this evolution of results was their own sense of guilt, their own desire for marriage, their need to do something, the unexpressed and unrecognized anger at their hitherto loving, permissive parents, their outraged feelings at the parental rage and demands that they obey parental commands, and the suggestion of the friend that they seek "tranquilization." All this had so disturbed their emotions that they were left in an essentially irrational state. The author then simply and deliberately employed their own state of irrational thinking to effect a favorable outcome by the use of a hypnotic technique—the presentation of ideas in a fashion conducive to acceptance despite their overwrought emotional state. Additionally, that technique of suggestion, unwittingly to them, subtly transformed the problem from "we must get an abortion" to "we must not think of a name for the [our] baby." This could only be a losing battle, and

the very desperateness of their efforts not to think of a suitable name could only serve to bring them closer and closer to marriage—as, indeed, it did.

Impotence: Facilitating Unconscious Reconditioning

Milton H. Erickson

Unpublished manuscript, 1953.

THE PROBLEM

The patient was a 42-year-old physician, actively and successfully engaged in the general practice of medicine. With much embarrassment he doggedly gave the history of his complaint. It was, he declared, "psychogenic impotence," and he knew that this was the correct diagnosis since he could and did masturbate with ease and he could maintain a state of full tumescence up to the moment when sexual relations became an immediate possibility. Detumescence, but without ejaculation, resulted at once if any effort were made at vaginal insertion or even at intercrural placement. He could be masturbated successfully by a woman if it were done manually. Enfoldment of his erect phallus between a woman's breasts as a masturbatory measure led to immediate detumescence, even as did the mere suggestion of fellatio.

This problem, he stated, began in his first year in college. Together with friends he had visited a bawdy-house, but without success, although he had told his friends otherwise. Thereafter, he had secretly visited the same and other bawdy-houses, "always with the same humiliating failure. I could walk a mile with a full erection, choose the girl I wanted, go to the room with her O.K., undress, and start to get into bed with her, and then, kerplop, just like dropping a baseball bat, I'd lose my erection. That, literally, is the story of my life."

He continued his account by relating extensively his efforts at self-therapy. He had visited innumerable professional and clandestine prostitutes and had offered them large rewards all to no avail. He had engaged in campaigns of seduction of girls he had been informed were permissive, but however successful his campaign the desired result was not achieved. He had sought out women of the other races without achieving his goal. He had ventured "to try community stuff," which meant several men and several women all engaged at the same time in the same room in various forms of sexual activity with a repeated interchange of partners. All that he had achieved was successful manual masturbation of his partner, while she successfully masturbated him manually. He had once attempted to approach a "swish homosexual," but this had been so offensive an idea that he could not bring himself to make even a verbal approach. He had served overseas in the armed forces, but "I was in combat service repeatedly with casualties all around me without ever getting wounded, but sexually I was a total casualty before every engagement overseas."

He had tried alcohol in various amounts to overcome his difficulty, and before graduating from medical school he had sought out "hopheads and got hopped up with everything they recommended, but it was all no good."

After graduation from medical school and the completion of his internship he had searched the medical literature extensively and had experimented with every drug preparation that seemed to offer even the slightest hope, but all to no avail.

He had tried two other measures: stage hypnotists, whom he soon came to regard as patently fraudulent because of their extensive claims unsubstantiated by any scientific knowledge or results, and "bedmates," attractive, willing women he paid to sleep regularly with him over a period of many weeks, in the hope that "sooner or later," he might awaken with an erection during the night and succeed in having relations. This measure also was a failure.

His reason for seeing the author was twofold. In the first place he had been aware that ever since World War I medical interest in hypnosis as a scientific modality had been growing, and he was aware of the author's interest in medical hypnosis. Secondly, six months previously he had fallen "desperately in love" with a 32-year-old woman who had responded to him as intensely as he had to her, with mutual declarations impulsively made by the end of three months of their acquaintanceship. This had forced him into a full confession of his sexual incompetency, although not of the extensive "therapeutic" measures to which he had ineffectually resorted.

She was appalled by his difficulty, but she was convinced that their intense emotional regard for each other would constitute an effective cure. He was doubtful of this, but after several weeks of persuasion by her he agreed reluctantly (since he feared the outcome) to let her discard her moral standards and sleep with him. Approximately a half-dozen futile attempts were made to effect his "cure" by her proposed method.

They then discussed the possibility of a happy marriage with only sexual play and affectionate embraces; but, despite her belief in such a possibility, he felt that the frustrations entailed would inevitably result in marital discord. They finally decided "to date regularly without any attempt at sex, but this was frustrating too."

Then one day he happened to read an article on the surgical use of hypnosis, and this led him to secure an appointment with the author.

Having listened carefully to his story while making adequate notations, the author told the patient that his problem would require at least two weeks of thoughtful study before any opinion could be reached, and that he might then request another appointment.

TRANCE INDUCTION WITH THE CONSCIOUS-UNCONSCIOUS DOUBLE BIND

For the next two weeks much time was spent mulling over the nature and character of the patient's circumscribed, rigid, fixed neurotic behavior and the measures by which that distorted pattern of sexual behavior might be reordered constructively. At the end of this time the patient was seen and informed that therapy would be undertaken, that hypnosis

would be employed, but that in no conceivable way would he have any comprehension of what was being done or of how it was being done. Instead of his having any intelligent appreciation of his therapy, he was to be blindly, stupidly obedient to every instruction given to him by the author.

He looked puzzled but nodded his head affirmatively while sitting quietly and expectantly in his chair. Then he was then told:

> As you sit there, close your eyes; listen intently to everything I have to say. Ask no questions; you have nothing to say. You are to develop whatever degree of trance is necessary, and that is what you are to do all the time you are listening to me. The only thing that is important is what I have to say, so listen intently with both your conscious and unconscious mind, especially with your unconscious mind, letting your unconscious mind take over more and more completely as you listen intently. It is not necessary for you to remember consciously, because your unconscious mind will remember what I say and what is means, and that is what is necessary. I shall tell you things you are to do, and do them you will, doing them as certainly as you are hearing me and being bound to do them as much as you are bound to hear them, and hear them you will, and do them you will.
>
> So listen intently, ever more intently, going into that necessary trance to hear me the better by your unconscious mind, which can alone assure that you will listen, hear, understand, and then act. And that you will.
>
> First of all there is to be no discussion, not even with M—. I and only I will discuss with M—.
>
> Next, you must and will arrange with your colleagues and the medical society and your answering service that you will take no night calls for the period of three long long months. [Many times in his story he had made mention of two three-month periods.] Nor will you take calls before eight in the morning.
>
> If necessary, simply take a three-month vacation from your medical practice just to do what you must do. But do it you will. Now listen with continuing intensity. Each morning you will note the calendar date, and each morning as you note the calendar date you will realize that day will end at midnight, and at midnight, every one of those midnights, for exactly three, three long intolerable months at the stroke of midnight up to the very end of those three long long months, you will know exactly what you are to do, and do it you must, and do it you will, up to the very end of those three intolerable long long months.
>
> Now listen yet more intently. At the stroke of midnight for three long months, and only three long months, and for exactly and precisely only three long months, you will drop into sound physiological sleep at the stroke of midnight for each night of those three long months. And do it you will, for each night of those three long months, each night, no more, no less, for three long months.

> Still listening intently, obediently, mindfully, and well. Each day you will dine with M— at exactly 8:30 P.M. Following this you may converse with M—, listen to music, or watch television—whatever you wish so long as you engage in no sexual activity whatsoever. Then, exactly at 11:00 P.M. you are to be in bed and the light turned off at exactly 11 o'clock. Not one minute before, not one minute later, but at exactly 11 o'clock the lights are to be turned out.
>
> There you will be, lying quietly on your back in the dark, saying nothing, doing nothing but lying there waiting for the stroke of midnight so that you may fall asleep in sound, restful, physiological sleep. And as you wait, tumescence will develop fully, and you will know, know thoroughly and well that you can do nothing at all about it, that you will not even try or even hope to do anything about it. All you can do is to lie there with full tumescence, waiting to fall asleep at the stroke of midnight, and this you will do for three long months; exactly at the stroke of midnight you will fall sound asleep in physiological sleep. Then, when sound asleep, and only then, can detumescence occur. Only then can detumescence occur, only then.
>
> Now, once more, maybe twice more, I shall repeat instructions as you continue listening intently in your trance, and then when I open the door, you will gently arouse and quietly leave. One final understanding that is to be achieved by you and you alone is that three long months is intolerably long, even as would two months be intolerably long, even as one month would be intolerably long, and all you need to know or to understand is intolerably long, whatever that means to you, so now listen while I repeat my instructions.

The instructions were then repeated verbatim, altering only the emphasis to effect, if possible, better unconscious understandings by the patient.

POSTHYPNOTIC BEHAVIOR INDICATING TRANCE DEPTH

At the expiration of the session the patient departed alone in a state of self-absorption. He apparently did not recall that Miss M— had accompanied him to the office at the author's request. Nothing had been said to him about seeing her also. It was for this reason that the author preceded the patient out of the office so that she might be signaled not to attract his attention. The author had hoped for such posthypnotic behavior on the patient's part, but considered it unwise to suggest it. Its spontaneous appearance indicated the depth and effectiveness of the patient's trance. Had such behavior not appeared, the experimental procedure would have been repeated immediately to secure more intense hypnotic responses.

TRANCE INDUCTION AS "DEEP SLEEP"

After the patient left, Miss M— was called into the office. To take advantage of her bewilderment at being so obviously forgotten by Dr. B., an explanation was offered: "I

have just been working hypnotically with Dr. B. in relation to the problem that concerns the two of you so much. So just be seated there in that chair, close your eyes gently, and go deeply asleep in a deep hypnotic trance."

Within a few minutes she was obviously in a deep hypnotic trance, and a presentation of instructions to her was easily made for which she developed a subsequent posthypnotic amnesia and full obedience. Her instructions were rather simple but very explicit. She was told to avoid quietly and unobtrusively any form of sexual behavior with Dr. B., to avoid even any form of affectionate physical contact with him, to be unquestioning of all of his behavior, to have dinner ready to 8:30 P.M. without fail, and to be in bed ready to go to sleep at 11 o'clock sharp, since Dr. B. would unquestionably turn out the light at that exact moment. Then in the dark she was to go to sleep quietly, comfortably, and in an expectantly happy state of mind that would be continuously present whether she were awake or asleep. All conversations were to be on topics unrelated to Dr. B.'s problem. Even if he should mention it, there was to be no discussion on her part. Since they had been living in the same apartment for some time, this was to be continued on literally a sister-brother relationship, so that she would lie quietly on her side of the double bed, contrary to her previous practice.

She was assured that all of this was utterly vital to the correction of Dr. B.'s problem.

She seemed to accept all instructions readily and to be quite passive in her attitudes. She left the office manifesting an apparent amnesia for the events of the office visit and for the manner of her arrival at the office. She accepted as a matter of fact the calling of a cab to take her home.

The Results

Just 30 days later, after office hours, both Dr. B. and M— appeared unexpectedly in the office. His opening statement was simply, "I would like to introduce you to my wife."

There then followed a somewhat disordered account, which was noted in full by the author and subsequently put into a more coherent form for this presentation.

> You know the problem I came to you for and explained in such great detail. Then I came again about two weeks later, bringing M— with me. I really don't remember much about that visit except that you began talking to me. M— tells me I forgot to take her home. But I do remember what I did. There was a young resident I liked very much who had just completed his residency. I asked him to take over my practice completely, because I had to be unavailable for about three months. I told him all income was to be his, and that if it wasn't sufficient, I would make up any additional reasonable amount. Everything turned out O.K. for him.
>
> Then I took a leave of absence from the office, but M— and I continued to live in the apartment. We went water-skiing, swimming, dancing—but not much of that

because our evenings were so funny. Even when we dined out, we always sat down at the table at 8:30 and ate, even if it was no more than a sandwich or some fruit. Neither of us said a thing about this. It just seemed to be a way of life, no matter where we had been that day. Since we are hi-fi addicts, we usually played records. I've got a large collection, and we enjoyed them a lot. Once in a while we would watch television. I even had my telephone disconnected.

But the funny thing was that we both had a compulsion to be in bed ready to sleep at 11 o'clock. We never kissed good night. We didn't even say good night. Sometimes we were in bed a few minutes before 11, and I would watch the clock, and when it was exactly 11, I would snap off the light. We were like a couple of dummies. We were living a queer sort of way without even thinking about asking why.

And every night after I turned off the light I'd get a full erection, but I would just lie there not doing anything about it, just waiting until it was midnight, because I knew that I could fall asleep then and that I wouldn't lose my erection until after I fell asleep. I was just a zombie. I just didn't do any thinking. I just acted like an idiot.

Then the other night [inquiry disclosed it to be the 27th night of the suggested three-month period] after I had turned off the light and developed an erection, I suddenly realized that I was unusually wide awake and that I just couldn't go to sleep. Then while I was trying to fall asleep and couldn't, it dawned on me that I couldn't lose my. erection until I did fall asleep. While I was wondering about this and still trying to fall asleep, I suddenly realized what it meant that I could not lose my erection until I fell asleep, and I suddenly exploded and I began making love to my wife. —Yes, we went to Mexico the next morning and got married, honeymooned the next day and night at a motel near Tucson, and today came in to see you. —Well, we just kept on making love until we both fell asleep. When we woke up, we were too excited to think about anything except getting married in Mexico right away. Then we honeymooned, as I said, but today on the way back to Phoenix to get an Arizona license to marry, we got to discussing what really had happened. But M— can't give much information, and what I know mostly is that I was hypnotized in your office and you told me what to do from day to day. But the important thing seems to be something that I'm confused about. It's that three months is just as intolerable as two months and two months are just as intolerable as one month, and there's something about understanding what intolerable really means. I don't suppose I need to know since I know I'm over my problem, but I am curious and so is M—. Both of us are completely satisfied, but we both feel that even if we don't know nothin' from nothin', it won't upset the applecart if you let us in on what happened.

They were asked if they wanted all the details or if they would be content to know that hypnosis had been employed to set up certain psychological patterns of behavior that would resolve the entire problem. To this was added, "To ask me to explain is like a

surgical patient asking the surgeon to explain a gastric resection." To this Dr. B. replied, "You may add that your patients are progressing postoperatively in a most favorable fashion."

More than five years have passed. The marriage has been a happy one. There are no children, but children were not wanted by either. From time to time Dr. B. refers a patient to the author or telephones the author to give special information about a referred patient and then to converse casually about matters in general.

DISCUSSION: HYPNOTHERAPY VIA PSYCHOPHYSIOLOGICAL CONDITIONING

To discuss what was done for this patient requires oversimplification and general interpretations. The patient had experienced an unfortunate mishap in a situation of mixed, varied, and guilty emotions, which resulted in a distressing and embarrassing frustration. He sought to correct his mishap by returning to the scene of his misfortune, only to repeat the same unfortunate behavior again. Why it happened in the first instance can be attributed to mixed emotions and inexperience. Why he returned to the place of misfortune can be attributed also to lack of experience and to a misdirected effort at self-help. The second recurrence of his mishap was simply a repetition of his first learning, believing naively that his difficulty could be corrected only by more repetitions of self-help. At some one point in all those 22 years of frustration he reached the conclusion that an unhappy, meaningless detumescence constituted an absolute certainty for him, and he maintained that conclusion. For him detumescence must follow upon tumescence without intervening experience. He became practiced in this sequence of events and learned no way of altering it. To state the situation concisely, he found himself caught in a psychophysiological bind that led only to hopeless frustration, a learning he endlessly reinforced.

Now what was done therapeutically? The nature of his problem was assumed to be a frustration deriving from what, for convenience's sake, was regarded as a psychophysiological conditioning that would not lend itself to any recognizable therapeutic endeavor. He had had too much unfortunate experience to accept a contrary belief. Therefore, it was decided, that therapy might be accomplished by setting up a second psychophysiological conditioning contradictory to his traumatic conditioning. This would have to be done with the patient's full cooperation but without his understanding of what was occurring. Thus, a pattern of behavior was suggested hypnotically (hypnotically because "no one in his right mind would accept such silly suggestions in the waking state," where too often the needy listener sets himself up as a final judge despite any degree of ignorance). This proposed pattern of behavior permitted tumescence and conditioned any detumescence to the development of full physiological sleep. Conversely—and this could not be recognized—tumescence was conditioned to the wakeful state. Only by falling asleep could he lose his erection; conversely while he was awake after 11:00 P.M. tumescence had to persist.

Then came the task of working out the details of behavior that would permit this reconditioning, then the task of obscuring the reconditioning to protect it from destructive recognition. At the same time provision had to be made to ensure, within a reasonable time (what was reasonable the author did not know), that the patient would find himself inexplicably confronted by the new state of affairs with no comprehensible way of resolving or understanding the bewildering turn of events except by "doing what comes naturally." So strong was the reconditioning that "doing what comes naturally" was terminated by complete satisfaction and restful physiological sleep, exactly as he had been intentionally reconditioned in this regard.

Once his goal had been so happily and well achieved, his problem could no longer exist. This the author knew before he undertook the case. The only problem was how to facilitate human behavior in a manner to lead to certain goals, to guard against interference by awareness of what was being done, and to create a slow, progressive development of emotional tensions (understanding what "intolerable really means") that would result in a state of uncomprehending awareness of a reality that could only be met adequately by activity favored by the state of passivity so thoroughly instilled in Miss M—. Thus, they achieved their actual goal. Just how that suggested behavior led to the final result is, at best, merely speculative. The discussion offered above seems to be a fair account of the author's understandings.

Latent Homosexuality: Identity Exploration in Hypnosis

Milton H. Erickson

Unpublished manuscript, 1935.

A social service worker, Miss X, who had been supervised by the writer in her work and who had, at various times, acted as a demonstration hypnotic subject, decided to be psychoanalyzed because of personality problems. What these were she could not state, other than to declare that she was hostile, antagonistic, exceedingly aggressive, unable to adjust socially, and most unhappy because of periodic depressive reactions.

After a year of "classical" psychoanalysis, five hours weekly, she sought an interview with the writer on a Saturday morning. Her reason was that she had "wasted" the year of analysis in "stupid resistance." For the past three months she had spent each session either in silence or in giving accounts of her daily reading of current books and magazines, and she had not discussed anything pertinent to herself. She asked that the writer put her in a trance and "force" her to "get down to business." Otherwise, since her funds were being rapidly dissipated, she would have to discontinue analysis. In fact, she had twice discontinued analysis but had returned after a week's absence, each time in the hope of doing something other than "showing resistance." On this occasion, however, she had informed the analyst that, unless results were forthcoming within the next three sessions, she was terminating therapy.

She was informed that the writer could do nothing about her request, since she was under the care of another physician. She was rather angered by "such ethics," but accepted the refusal. She declared that she felt entitled to ask such a favor from the writer because of her services as a hypnotic subject in the past. This led to the writer's request, that, as a favor, she would again act as a demonstration hypnotic subject for a lecture before a medical group to be given that afternoon. She consented, commenting that it was apparently all right for the writer to ask a favor but that it was "unethical" for her to do so.

TRANCE INDUCTION AND HYPNOTIC ROLE-PLAYING

Since the writer knew her well, he had formed a private clinical judgment about her personal problem. Also, he was thoroughly acquainted with her officemate, Miss Y, a most feminine girl. Accordingly, at the lecture she was deeply hypnotized and, among other things, depersonalized, then induced to assume the identity of Miss Y. She did this in a startlingly accurate and impressive fashion. As Miss Y, she expressed an intense dislike for Miss X, but could give no reason for this attitude. When the demonstration of this and other hypnotic phenomena had been completed, she was awakened, thanked and dismissed with a posthypnotic amnesia for the trance experiences.

She was seen a week later, very happy and excited. Her story was that she had kept her Monday appointment with the analyst and spent the first half-hour in sullen silence. Then, suddenly, the thought of Miss Y came to her mind, and this had loosed a whole flood of free associations. For the first time in her analysis she became communicative. Each session thereafter had been most productive. She stated that she was now making progress and that, when her analysis was completed, she would inform the writer of the nature of her conflicts.

Three months later she was discharged as requiring no further therapy. Shortly thereafter she sought an interview with the writer, explaining that she attributed the success of her analysis more to the writer than to the analyst. Also, for some reason, Miss Y should be credited in part, although she had disliked Miss Y until recently. However, therapy had corrected her dislike. She continued by explaining that her personality conflict had centered around "strong latent homosexual tendencies," which she had not recognized and which she had repressed with "every ounce of my strength." Because of those tendencies she had reacted with bitter hostility to men and to women in general, especially attractive, highly feminine girls such as Miss Y. Once this material came forth in free association in analysis, she made remarkably fast strides in her adjustments.

She concluded her account with the statement that she was confident that the writer and Miss Y, in some unusual way, had made it possible for her to recognize her problem and to free her of the repressions. Beyond this statement she could explain no further. She asked if any explanation could be given to her.

She was hypnotized and asked if she still wanted an explanation of her conscious belief. She confirmed her desire. Accordingly, she was instructed to remember all of the events of that Saturday-afternoon demonstration. She did so easily in chronological order, reporting her recovered memories readily until she reached the point at which she had been depersonalized and induced to assume the identity of Miss Y. Then she paused and, after much thinking, declared, "So you knew what my problem was all the time. And you made me become a feminine woman. And you made me enjoy it. And I did enjoy it. It was wonderful. I felt so good and so relaxed and so comfortable. And when you changed me back to myself and awakened me, I woke up so mad that I wanted to slap you. I was so glad when you told me I could leave because I was afraid I was going to slap you. I didn't know why. I couldn't sleep that night, and all day Sunday and Sunday night I was horribly depressed and angry. Monday afternoon at my hour session I was just mad at everything, nothing in particular. Then I happened to think of Miss Y, and that opened the floodgates. My analyst was so pleased that I had broken through the resistances. Now I can see that you recognized my problem, that you deliberately forced me into a position where, when I was Miss Y, I could think about myself as a stranger. I told you then I didn't like me, even though I didn't know it was me I was talking about. But I really saw me and it wasn't pleasant—all those repressed homosexual fears and conflicts."

"Then in that hour when I started to free associate, I really could do it! My analyst was so pleased, too. Any time you want to use me as a subject, you can, I owe you so much."

She has since married happily and is enjoying a career other than social service work, combining it with rearing a family. Subsequently she explained her reason to the writer for abandoning social service work, which was her realization that her original interest in such work was primarily a search indirectly for therapy and, at the same time, a denial to herself that she needed therapy.

Vasectomy: A Detailed Illustration of a Therapeutic Reorientation

Milton H. Erickson

Unpublished manuscript, circa 1950s.

A college graduate in her early thirties, with three children, was married to a professional man. She sought psychotherapy because of what her husband described as "sexual obsessions" that had come to dominate their daily life during the past two years. These centered around an insatiable curiosity about the love affairs of people she knew and those she read about in the newspapers. The husband could not understand her "incessant talk" on the subject, since they were well-adjusted and active sexually. Nor did she have any doubts about his fidelity, since he had confessed his premarital experiences and had had no desire for extramarital experiences since marriage. Neither did she have any suspicions regarding him. However, she was convinced, and this was confirmed by her husband, that several permissive women had undue interest in him. One of them had actually suggested a liaison, should he be interested.

In discussing their sexual adjustments both husband and wife disclaimed any disharmony. After the birth of the third child they agreed on vasectomy as the most convenient method of birth control. The operation had been done four years previously when the youngest child was five years old. There had never been any feelings of regret experienced so far as either knew. They were entirely satisfied by the size of their family and relieved by no further concern about precautions for birth control.

The first part of therapy for Mrs. A was devoted to her explanation of her curiosity. Newspaper stories, neighborhood gossip, and general speculations constituted her communications. Next she began offering an extensive, well-organized, elaborate discourse upon the significance of sexuality in adult daily marital and family life in establishing emotional bonds and a sense of personal fulfillment. After several hours of this she declared that obviously she was making no progress and that she had decided that there was much in her unconscious that she was repressing and concealing by an avid interest in external matters. Therefore, she felt that hypnosis should be employed and that her unconscious should be encouraged to give free rein to expression.

THERAPEUTIC TRANCE AND POSTHYPNOTIC SUGGESTION

She proved to be a fair subject and readily accepted posthypnotic suggestions that she talk freely and without attempting to give orderly ideas. Upon awakening, she announced a full recollection of what had been said to her in the trance, declaring that she would not act as had been suggested. Instead, she had decided to speculate freely upon how a woman would think, feel, and act in considering how to establish a liaison. She then

described various men she knew, speculated upon their attributes, general attractiveness, sexual prowess, capacity to establish emotional relationships, possible attitudes toward liaisons, and numerous other considerations. Next were considered places, times, physical settings, social settings, and the general atmosphere in which a liaison could be culminated.

This was followed by an extensive consideration of the emotional effects and results of a single extramarital experience and the results of a continued affair. She discussed well and comprehensively the effect of liaisons upon the individual lives of the participants, their family relationships if they were married, their individual emotional lives, the influence of past training and conditioning, and the immediate and subsequent developments. This was followed by a consideration of guilt feelings, their impingement upon the individual aspects of life, upon the liaison itself, and the separate family lives.

Thereupon she began discussing in detail how she would react in establishing a liaison, how active and how passive a part she would take, and what she felt would be the ultimate outcome. Her conclusion was that she was certain she could adjust happily either to one single sexual experience with a highly desirable, respectable man, or to a discreetly conducted affair of at least a year's duration with a similar man. Usually an hour or two, sometimes more, was necessary to complete her discussion of these various topics. During them she was remarkably objective and serious in all of her remarks.

The next development was her declaration that she had only been "stalling for time without knowing it." She explained that all of the previous discussion had been but a slow introduction to the really important things she had to say. Thereupon she lapsed into a troubled silence, after explaining that she knew what her trouble was but did not have the courage to state it. The next hour was also spent in silent emotional distress.

At the next appointment she began with the assertion that she might as well begin to disclose her problem, which she had not previously recognized until she had remarked about "stalling for time." She then asked permission to speak frankly and freely. When this was granted, a torrent of words poured forth in the language of the street. In essence she declared that she was an adult woman, a married woman, a woman who had borne children, that she was a sexualized female, and that, as a healthy normal living creature, she was entitled to have her biological needs and hungers completely satisfied. Therefore, as a living healthy normal female, with healthy normal appetites, she was entitled to be satisfied by a male who was completely a male and not one who was "expurgated" or "bowdlerized." He did not have to have two legs or even one, nor two arms, nor even two testicles. All that he had to have was enough penis and testicular tissue to be able to ejaculate semen—live, potent semen—upon or in her genitals. Thus, and only thus, could she have the biological satisfaction of being a sexualized female. She did not want more children, she had no desire to become pregnant, but when she had intercourse, she wanted to have it with a man capable of impregnating a female and not capable of only simulating such an act. In fact, she had never objected to contraceptives because the capacity to impregnate existed, and therefore a biological potency existed.

She had not realized that a vasectomy would constitute so serious a deprivation for her. In fact, she had not even been aware of such a possibility. She had first looked upon vasectomy as a simple solution to a minor nuisance, but after a year a growing unrest and dissatisfaction had developed. She had met this by increased sexual activity and ardor, to her husband's great satisfaction and the seeming happiness of their sexual adjustments. As her vague unrest developed, she had first reacted by dropping some old friends and replacing them with new acquaintances. As she looked back, she realized that the rejected friends were either unmarried or childless couples and the replacements were couples with children. Additionally, she had developed a predilection for people who were grandparents, particularly those whose sons had borne children, thereby signifying a continuance of masculine biological potency.

Also, as she reviewed the men she had considered as possible lovers, every one, whether married or divorced, had fathered children. The only single man in the list had been involved in a bastardy case. In her obsessional interest in love affairs, rumored or published in the news, the only ones that had interested her were those of men, married or divorced, who had fathered children. She went on to declare, in direct Anglo-Saxon terms, that the essence of her problem was a compelling desire, once more, to have sex relations with a biologically complete man, even at the risk of an illegitimate pregnancy. This last assertion was taken as a point of departure in summarizing her problem for her. Accordingly, the following discussion was offered:

1. What she wanted was an emotional experience, an emotional satisfaction, a satisfaction related entirely to her inner needs.
2. The question of risks involved, of times, places, physical setting, social atmosphere, etc., were all unimportant, since the problem was one of her emotional satisfaction.
3. The man himself would be no more than an instrument, that it was not a part of her need to establish an emotional bond, such as marriage and a home, that all she desired was her own response to a specific stimulation that could effect a satisfaction of her emotional needs.
4. Therefore, her problem did not center around the giving of sexual satisfaction, but the gaining of complete sexual satisfaction at an emotional level in relationship to a man.
5. Hence, it would not be necessary for the man to do anything or to provide anything actually material to her sense of complete sexual satisfaction other than to be a potent male. His potency as a procreator would be the only important consideration.

The patient was most attentive to these ideas, and care was taken to prevent her from analyzing them too closely. The suggestion was offered that they ought to be presented in detail to her unconscious mind to permit an even more adequate understanding of them. She agreed and developed a definitely better trance than before and listened attentively to the discussion offered her a second time of the above ideas. Thereupon the suggestion was offered that her needs could be met in a remarkably adequate fashion and in a manner that would please and intrigue her without emotional repercussions of any sort.

She was urged to accept this idea of this possibility, even though she did not know exactly what was meant. She asserted that she would do whatever was asked.

POSTHYPNOTIC SUGGESTIONS FOR THERAPEUTIC DREAMS AND FANTASY

The explanation was then offered that that night she was to sleep most soundly and, during her sleep, she was to dream vividly of the past. This dream was to center around a period of time just previous to the conception of any one of her children (they were all "planned children"). The dream was to be most vivid and active, and it could be as erotic as she wished. Upon awakening the next morning, she could, if she wished, remember the dream. On the second, third, and subsequent nights she would continue to have similar and even more vivid dreams.

At her next appointment she reported that her dreams had been as suggested and that in them she had relived previous satisfying experiences with her husband. As a result of her dreams her sexual appetite had increased greatly, but nevertheless she still had her compelling drive. A new series of posthypnotic suggestions was given her. This time, in addition to her nocturnal dreams, she would, upon awakening, recall them and engage in a fantasy about them. Thus, she would suddenly discover, during the fantasy, that sexual excitement was developing, culminating spontaneously in an intense orgasm.

When seen four days later, she related this new development. Her first fantasy had been a recollection of her courtship days. She had been suddenly overwhelmed with excitement and embarrassment upon recalling a specific instance in which the question of premarital sex relations had been discussed, and she had reacted by experiencing a violent orgasm.

The next morning, while recalling her dream, she chanced to see her husband's photograph on her dresser. This had been taken just shortly before the conception of the second child. Upon looking at it she developed sexual excitement, which culminated in an orgasm. Later that day she had taken out an old photo album to look over her collection of snapshots of her courtship days. In so doing, she came across the picture of a former admirer, now married and the father of several children. To her amazement she became sexually excited and had an orgasm. This had astonished her so much that she "did not know what to think," and she remained preoccupied and self-absorbed throughout the rest of the day.

That night, after satisfying sex relations with her husband, she fell asleep comfortably and began a series of dreams. In each dream she saw, spoke to, or merely thought of various men, and as well as she could remember the dreams, she had in each instance experienced an orgasm. Then in the morning, when wide awake and reviewing her dream behavior, she had deliberately chosen to fantasize about one of the men she had previously named, and had been delighted to experience an orgasm as a result. That afternoon she picked up her husband at his office. While waiting for him, she had greeted his business associate, a married man with a large family, and had quietly and immediately had an orgasm. That evening she had insisted that she and her husband call

on a married couple she admired greatly. While playing cards with the host as her partner, she had an orgasm.

Since then she had been thinking things over, and she felt that she now had no problem of any sort. She had, she explained, a feeling of inner conviction that she was truly a biological female, capable of responding adequately to any biologically competent male at any time she chose and in a way that met her needs adequately without creating problems. In the two years that have elapsed since the termination of therapy, she has been seen on occasion for advice concerning her children. As for her problem, it no longer troubles her. She feels free to have her own sexual response in her own way, but usually she resorts to a dream, almost invariably about her husband and in relationship to the time of planning for a pregnancy.

Pseudo-Orientation in Time as a Hypnotherapeutic Procedure

Milton H. Erickson

Quoted from the *Journal of Clinical and Experimental Hypnosis*, 1954, 2, 261-283.

In every attempt at psychotherapy there is always the need to utilize the common experiences and understandings that permeate the pattern of daily living, and to adapt such utilization to the unique needs of the individual patient. Hence, to a significant degree psychotherapy must necessarily be experimental in character, since there can be no fore-knowledge of the procedures exactly applicable to any one patient. Furthermore, the entire field of psychotherapy, in itself, is still in the course of early development, thereby enhancing the need for continued experimental studies.

For these reasons the following case histories are reported to illustrate an experimental therapeutic technique employed by this writer from time to time for the past 15 years. This technique was formulated by a utilization of those common experiences and understandings embraced in the general appreciation that practice leads to perfection, that action once initiated tends to continue, and that deeds are the offspring of hope and expectancy. These ideas are utilized to create a therapy situation in which the patient could respond effectively psychologically to desired therapeutic goals as actualities already achieved.

This was done by employing hypnosis and using, conversely to age regression, a technique of orientation into the future, or "time projection." Thus, the patient was enabled to achieve a detached, dissociated, objective, and yet subjective view of what he believed at the moment he had already accomplished, without awareness that those accomplishments were the expression in fantasy of his hopes and desires.

PATIENT A

The first of these case histories is that of a 30-year-old divorced man who held a minor clerical position, lived in a wretched rooming-house, and had no friends of either sex. He did no reading, did not attend church or the theater, ate all his meals in one cheap restaurant, and limited his recreation to aimless driving about the countryside.

For three years he had been under the care of a general medical man because of innumerable somatic complaints involving all parts of his body. At one time he had been hospitalized as a possible candidate for abdominal surgery. He had reacted traumatically to his admission to the surgical ward by developing extreme terror, sobbing, screaming, and complaining of agonizing abdominal pain. An exploratory laparotomy disclosed no

pathological condition, but a routine appendectomy was performed. His convalescence was prolonged for a month and marked by even more complaints than he had expressed previously. Additionally, he was periodically depressed, cried a great deal, and was most reluctant to leave the hospital. The operation and his related behavior convinced him that he was a "coward," that he was "no good," "worthless" and "incapable of being a man."

Thereafter he had functioned at an even lower level personally and economically. He visited his physician two to four times a week, plaintively seeking help for his weakness, backache, headaches, gastric pains, etc. Efforts to refer him to psychiatrists proved futile. They "did not understand" him. In turn, the psychiatrists variously reported him as a "character defect," an "inadequate personality," a "profound hypochondriac," and a psychopathic personality of the constitutional inferior type." All agreed that he was not amenable to therapy. However, the writer's clinical impression was much more favorable.

Approximately 18 months after his laparotomy, he was referred to the writer for hypnotherapy, and the extensive case history which his physician had taken was made available.

Rapport was easily established with the patient. He was pitifully eager to be hypnotized, and he proved to be a remarkably fine subject. For a month he was seen weekly for a three- to four-hour session. During this time all efforts were devoted to training him to develop readily every hypnotic phenomenon of which he was capable. For all of these sessions a profound amnesia was induced. No therapy was attempted other than establishment of good rapport and a general feeling of trust and confidence.

The next two sessions were spent having him hallucinate a whole series of crystal balls. [The idea of crystal balls lends itself readily to popular understanding, and hallucinated crystal balls are convenient, easily manipulated, and remarkably economical] In them he was induced to see a great array of the outstanding emotional and traumatic experiences of his life. These hallucinated portrayals were "fixed"—that is, he could look from one scene to another and back again without having to rehallucinate. Thus, he could see himself depicted in various situations and at different times in his life. Thereby he could observe his behavior and reactions, make comparisons and contrasts, and note the thread of continuity in his reaction patterns from one age level to the next.

A most extensive and elaborate series of events was thus viewed by the patient. His reaction to the total experience was one of hopeless resignation, "Anybody that has had all that happen to him ain't got much chance." Even after being awakened with an amnesia for each session, his mood was one of discouragement and general depression.

The next session was spent by having him discuss in the waking state all the things he wished for himself, the hopes he had, and all the ideas he had of what might be possible for him. This session was not satisfactory since much of the time was spent emphasizing his complaints as insuperable barriers to anything he could want. At the close of the session he was most discouraged.

At the next session he was hypnotized deeply and instructed to repeat the task of the preceding session. His wistful, plaintive hopes for the future can be summarized as follows:

1. The enjoyment of "just fair" physical health.
2. An economic adjustment "about average."
3. Personal adjustment sufficient so that he could "get along" in relation to recreation, personal habits, social activities, and personal interests and friendships.
4. "Not too much" fear, anxiety, and feelings of compulsion.
5. "Enough guts to be a man" if he ever had to have an operation, or, if he had to defend his rights, "to take a licking like a man."
6. A desire to be able to "take in my stride a little better" all the bad things that had happened to him or might happen in the future.
7. A wish that he could achieve "maybe enough" emotional maturity so that he could marry for love and not "because someone pitied me."

He was awakened with an amnesia and departed in a general depressed mood.

In the two preceding sessions, as in the previous sessions, no effort was made to do more than to elicit his responses. At the next session, with the patient in the waking state, a vague general discussion was elaborately offered of what he could expect in the future. This, it was explained, *would be the opportunity to look back over the past, to review his complaints and difficulties, and to recall the developments of therapy. Then, most importantly, he could examine all those accomplishments, resulting from therapy, that represented his achievement of those things signifying normal adjustments. However, this latter could be done only after a lapse of time, probably several months, following the termination of therapy*.

He was then hypnotized deeply, and the same discussion was repeated in similar general terms. Still in the deep somnambulistic trance, he was then disoriented for time and then oriented or projected in time[1] to some future date[2].

The projection into the future that this patient achieved was approximately five months, and the setting was an office visit. The purpose of his visit—since, for him, enough time had elapsed since terminating therapy—was to give an account of what had really happened since then.

The suggestion was offered, to which he readily assented, that he might like to begin with a brief but comprehensive review of the past as depicted in crystal-ball scenes. Some 10 minutes were spent by the patient in this hallucinatory review. During it his emotional manifestations were those of sympathetic interest rather than the intense fear, anxiety, and concern he had frequently shown in previous similar situations.

Then the suggestion was made that he might be aided in giving his report on the therapeutic developments he had achieved by visualizing the significant incidents in another series of crystal balls. Thus, he could enjoy watching the progressive unfolding of each event as it had occurred.

He agreed enthusiastically, and as he viewed the various hallucinatory scenes in the crystal balls, his enthusiasm and pleasure increased. Frequently he would either comment excitedly or demand that the writer observe what was happening.

Some of the reports he gave may be summarized briefly as follows:

1. I'm walking down the street. I'm turning. I'm going to see Dr. X (his physician). No, I'm walking past. I'm thinking, "Thank God, I don't have to go there again."
2. I'm swimming and—watch me, I'm going to do a high dive.
3. Look, I'm asking the boss for a raise. He's going to give it to me. Damn it, I couldn't hear how much. I don't understand that. (His attention was hastily distracted.[3])
4. My goodness! Did you see that? That was that great big lug who always parked his car just to be mean so I couldn't get my car out until he came out half an hour later. Now I'm telling him off and thinking what a sap I was to keep parking my car where he could pull that dirty trick.
5. I'm in the theater. (He was asked what the picture was.) Who's looking at the picture? I'm necking my girl.
6. That's a different girl and I'm taking her to the art gallery and then we are going out to dinner. She's pretty.
7. I'm giving a speech to a group of men. I wonder which one that is because I gave another speech, too, but I can't see plainly.
8. My car has been painted and I got a new suit. Looks good. I even wear it to work.

He was unwilling to discontinue his crystal-gazing, expressing much pleasure in his accomplishments and a desire to describe more of them. However, he was reoriented to the current time and given extensive posthypnotic instructions to have a complete amnesia for every possible thing that might have occurred during the session. Additionally, he was to make no response of any kind to any of the things that might have happened during the session except a full obedience to the instructions just given.

He took his departure, complaining of extreme fatigue.

He was seen the next day, and the same routine was employed. He was carefully oriented about seven months in the future, and he made a similar initial response to this projection in time.

He was addressed as follows:

> As I remember, I saw you last about two months ago. You came in to report upon your progress. I put you in a trance and had you visualize yourself in crystal balls so that you could give me full accounts.
>
> Now, suppose you remember tonight all the things you said and saw that night about two months ago. Never mind anything I saw or did; remember only the things you said and saw and did while you were giving me the report. [This was to prevent him from recalling anything about preliminary or subsequent hypnotic instructions, particularly in relation to time projection.]
>
> Now review all those things. Some of them go way back to our first meeting and even way back to the beginning of the problem you brought to me. Think them over carefully, clearly, extensively, and then discuss things for me.

The essential content of his discussion follows:

I was really a sorry mess when I met you. A whining crybaby. I don't see how you could have stood me. Dr. X deserves a gold medal for what he put up with. It embarrasses me to think about it.

> I don't really know what happened. It was like a dream, but it wasn't a dream. Whatever you said to be became true. I was a little boy, I was older, I was still older, sometimes all at the same time. Some way you made me live my life all over so I could see it. I really lived it, too.
>
> Then you made me see it in moving pictures in crystal balls. I was in the crystal balls. And I was outside watching. Some of the things I saw were pretty darn sad. But I was a sad sack myself.
>
> But the thing I really liked but didn't have any hope about was when you made me tell you all the things I wanted to do. Then somehow I began doing those things. I can't understand that because I must have been in this room and I wasn't. [He was immediately interrupted, and extensive hypnotic instructions were given that he report only on what he himself saw and did and that he was not to try to understand the situation.]
>
> Well, I did every one of those things. Surprised myself! Boy, I really felt good about it. I enjoyed doing them. I sure was surprised when I asked that waitress for a date. She's a nice girl. And that raise was $10.00. And when I told off that lug about blocking me in with his car, he took it like a man. And I felt like one! I've got to look up Dr. X some day because he was really interested in me. I guess he believed in me, even if he didn't help me.

He continued to review extensively, with confidence, assurance, and pleasure, a further wealth of fantasied accomplishments, all in keeping with a suitable reality situation for him. They all had, apparently, the significance of absolute realities for him.

When he had apparently finished, he was told that he was to be hypnotized. By this approach it became possible to reorient him to current time. Again, as in the previous session, he was given extensive posthypnotic suggestions to induce a comprehensive amnesia for trance events of all sorts.

Still in the trance state, he was instructed ambiguously that his next appointment was possibly for next week but that it might or might not be kept; that various events would develop which would determine both the time and the manner in which he would keep the appointment. However, he would certainly be seen again, if not next week, quite possibly in two months' time.

He was awakened with posthypnotic instructions for amnesia and dismissed with no mention of a future appointment. He appeared exhausted and self-absorbed.

He was not seen until eight weeks later. He arrived in a new suit, and his car was newly painted and had new seat covers. An attractive young girl, a secretary, accompanied him. His opening statement was that he felt that he would like to give the writer an account of the recent events that had occurred. His report may be summarized as follows:

> For about a week after the last session he had felt confused and bewildered, but at the same time he had a "feeling" that "something good was happening" to him. Then one day he had wondered about his next appointment while at work, but before he could clarify his thinking, he had impulsively asked his employer for a salary increase. Not only had this been granted, but he had been transferred to another and better position. This had given him a tremendous feeling of elation and self-confidence.
>
> Upon leaving work that night, instead of waiting in his car and raging helplessly, because he was boxed in, he hailed the man and invited him to have a beer. During the drinking he had told the man in a simple, matter-of-fact tone of voice, "I think you have been blocking my car regularly because I've been such a damn sissy. From now on, you damn bastard, cut it out and have another beer on me." This had ended that petty persecution.
>
> Much elated by this, he dined at a different restaurant that night, fell into conversation with a waitress, and asked her for a date. She refused but, unperturbed, he went to the theater alone.
>
> Subsequently he had moved to another and better residential section. In the process of moving, he "went through all the trash I've been saving for years. I threw out all the junk, I really cleaned house."
>
> He had joined a Young Businessmen's Club and had maneuvered himself into a position on the weekly program. He felt that he had acquitted himself creditably.

> From then on, "I began living a normal respectable life and enjoying things like an average man. I just suddenly got out of all my bad habits and feelings. It was easy once I got started. I just never tried that before. But one thing just naturally led to another and instead of feeling bad like I used to, I just get out and do something I ought to.
>
> I met my girl at a dance, and we're going steady. But we are going to wait awhile to see if we're really interested.
>
> My health is good. I don't pay attention to every little ache or pain the way I used to. You got to put up with a cold or something like that instead of getting scared to death. Some day I'm going to see Dr. X and let him see me the way I really am. He was a good scout with me."

After still further discussion, during which no effort was made by him to inquire into what had occurred in relation to the writer, he departed. He was seen casually from time to time thereafter in a social way. Two years later he was still adjusting satisfactorily, and he and the secretary were completing their plans for marriage.

PATIENT B

This case history concerns a long-continued, highly circumscribed form of compulsive behavior.

The patient's mother had died when he was 12 years old. His father insisted that the son visit the mother's grave and place flowers on it every Saturday, Sunday, and holiday regardless of anything except absolute physical incapacitation. On several occasions the boy had played truant and had been brutally beaten by the father, who had reacted to the mother's death by becoming a severe alcoholic.

When the patient reached the age of 15, the father, first giving the boy a most brutal beating to make him remember to visit the grave, had deserted him. For a year the boy had lived in the home of a distant, unfriendly relative before striking out on his own.

For 15 years, summer or winter, rain, shine, or snow, he made his pilgrimages to the grave, sometimes having to make regularly a round trip of 20 to 40 miles. Even during his courtship he regularly took his fiancée on the Sunday pilgrimage.

During the years physical illness had confined him to bed on several occasions and made him miss his regular trips. He had reacted by making extra visits during the week. The result had been a compulsion to make a daily trip. At the time of seeking therapy he was making a daily round-trip of 20 miles.

He had attempted to break the compulsion by placing bouquets of dandelions or wild chicory blooms from the roadside on the grave, even limiting the offering to a single bloom and then to none at all. However, the compulsion proved to be that of a visit only.

Then he tried to break it by merely driving past the cemetery and hurrying home. A dozen such attempts had caused him such extreme anxiety, insomnia, panic, gastric symptoms, and diarrhea that each time he had been forced to make a midnight trip to fulfill his "obligation."

His reason for seeking therapy was that he had recently been offered a most advantageous position in a distant city and the deadline for his acceptance was approaching. While both he and his wife were most eager to make the change, the thought of being unable to make the daily trip to the grave caused him to suffer intense panics.

Because time was short and his problem was circumscribed in character, intensive hypnotherapy was employed. He proved to be an excellent somnambulistic subject and was easily taught to manifest hypnotic phenomena.

In a deep trance he was asked to review his innumerable pilgrimages, his memories of his mother, and the nature and character of his feelings, particularly his resentments, toward his father. He found this a most difficult task and possible only if he did it silently. Hence, this approach was abandoned.

Accordingly, he was disoriented for time and systematically oriented by projection into time *two weeks in the future*. Essentially, a technique comparable to that used for Patient A was employed. During the process of orienting him in the future, elaborate instruction was given to him to ensure a calm, comfortable feeling and to induce an overwhelming interest in whatever the writer might have to say.

As soon as the new orientation had been secured, a casual conversation was begun with him and carefully guided to the subject of his remarkably good muscular development, of which he was exceedingly proud. This led to an extolling of the patient's adherence to his principles in not smoking or drinking and of living a good, clean, industrious, hard-working life.

When these ideas had been built up sufficiently, he was challengingly asked, apparently in a spirit of camaraderie, if he had the strength to stand up like a man under a shock. He replied that he could "stand up under anything that any man could dish out." This led to the writer's declaration that he could easily "floor" the patient "with a good wallop." Entering readily into the spirit of the verbal exchange, the patient declared that the writer did not have "enough beef." After still further similar persiflage, he was warned, "Pick a spot on the floor to take a tumble, because I'm going to hit you hard and unexpectedly. Listen, here it comes. Now listen! You are a beautiful physical specimen, you live right, you work hard, you are a string man, you are feeling good. Now here's the punch. Listen! *For two whole weeks you have not visited your mother's grave—not once for two whole weeks.* Are you alive, are you strong, or are you a weakling that I can lay out with my little finger?"

His startled response was, "Good god, how did I stop?"

Before he could elaborate that question, he was emphatically admonished that it was not the how, *but the fact the he had stopped that was of significance, and that he could now feel happy and relieved that it had been done.* Without a pause the writer continued with a rapid, general discussion of all the problems involved in packing, moving, finding a new home, and getting settled. The patient was admonished emphatically to work out these matters to the last detail, since it was a problem that would require every possible bit of energy.

Very rapidly, then, he was reoriented to the current time and awakened with extensive posthypnotic suggestions for a continued amnesia of all trance events. He was given an appointment in two weeks' time and dismissed. (Since it was known that his grave visits were a sore topic at home and never mentioned, no special precautions had to be taken.)

He reported promptly for his next interview and was cheerful and enthusiastic. He had accepted a new job; arrangements for moving were practically complete, and would be accomplished within the next week.

Special inquiry had been made secretly of his wife, who reported that, while he had worked regularly, he had been home each night approximately an hour earlier. Also, he had worked busily at packing the full day both Sundays as well as during all spare time during the two weeks.

Accordingly, his enthusiastic account of his new preparations was suddenly interrupted by the inquiry, "How does it feel to be happy, content, enthusiastic, and really interested in the new job and *few from having to visit your mother's grave*?"

In startled amazement he declared, "Good God, I haven't done that for two weeks. I've been so busy."

Immediately, by means of a posthypnotic due to which he had been trained to respond, a deep trance was induced.

As if there had been no alteration in his level of awareness, the writer replied, "Yes, now that you are asleep, you now know that you were too busy. More than that, *you know now by actual experience that you don't need to visit the grave anymore.* But, of course, if an legitimate occasion ever arises, you can do so in a normal way. Thus, on Mother's Day you could, or some such occasion."

After some silent thought he asked, "Is my father alive?" Reply was made, "Neither you nor I know if he is dead and gone; we know only that he is gone and that you are a man.

Return was made to the question of the new job, and after some further discussion he was awakened. At once he returned to the moment preceding the posthypnotic cue by remarking, "Two whole weeks! I don't understand it, but it's sure O.K. with me. Maybe taking that new job did something for me."[4]

Return was at once made to discussion of the new position, and shortly he was dismissed.

In the 10 years that have followed only on those rare occasions when he visited the hometown would he visit the grave, and then only if it were convenient. Also, there have been no other neurotic manifestations developed to replace the original compulsion.

PATIENT C

This next case history also concerns a circumscribed problem but of another type. Psychiatric help had been repeatedly sought and always rejected on the specious grounds that cooperation was impossible. The patient was a 20-year-old student nurse. When she was less than a year old, her mother had secured a divorce, broken off all ties with everyone she knew, moved to another state, and had destroyed every possible evidence of the father that she could.

As the patient grew older and inquired about her father, the mother simply stated that she had divorced him, that she knew nothing about what had happened to him since then. Additionally, the mother firmly refused to give any description of him or even to reveal the location of her former home.

Upon reaching the age of 18, the patient made a determined effort to learn something about her father. The mother's marriage certificate and divorce decree were locked, she was informed, in a safety deposit box and would remain there. As for the patient's birth certificate, it disclosed only that she had been born in Chicago. Her mother explained that her birth had been unexpectedly early and had occurred while she and the father were visiting some of the father's relatives in Chicago. As for the mother's maiden name, that, like the father's surname, was utterly commonplace and there would be no possible way of tracing identities.

Thoroughly frustrated by this, the patient had sought out psychiatrists who used hypnosis. She would demand that they hypnotize her and thereby compel her to remember something about her father. However, she would immediately establish an impasse by declaring that such a procedure would be ridiculous, since she had no memories of him. Hence, all that would be secured would be her "imaginations" and she did not want to have them passed off as genuine. She invariably refused to cooperate and at no time was she ever hypnotized.

When she came to the writer with the above story, her request was refused on the grounds that a search for memories before the age of one would be futile. (Actually, of course, she represented an interesting problem if her cooperation could be secured by a judicious use of negativism on the writer's part.) She was reassured by this refusal of her request, but before the interview was terminated, she had become interested in hypnosis simply as a personal experience.

Accordingly, arrangements were made to train her for "experimental work." She readily became an excellent hypnotic subject except for the one procedure of age regression. This

she would not permit, and when indirect efforts were made, she invariably awakened to protest that "things seem to be going wrong."

Therefore, the measure of projecting her into the future was decided upon as a possible approach to her problem.

Consequently, while she was in a profound somnambulistic state, an "experiment" was outlined for which she was to do some learning tasks. Then, it bras explained, she was to be projected into the future, and she would report upon that learning. Thus, the nature and character of her forgetting could be studied. However, as a "preliminary" bit of training she would first bb projected in time and induced to have fantasies of activities during the period of time between the current date and the future date.

Following these explanations (actually disguised instructions for her guidance), she was disoriented and then oriented to the future. No effort was made to ascertain the approximate date, but various remarks permitted the deduction that the time projection was about two months.

She was asked to give a full account of that "remarkably interesting patient" she had cared for since that "last interview with me quite a few weeks ago." She executed this fantasy and several others of a comparable character. During the narration of them mention was made repeatedly that she had probably forgotten a lot of the details, to which statement she was induced to agree.

She was then reminded that "quite a long while ago" arrangements had been made to study her rate of forgetting and that the time had now come. Speaking rapidly to ensure her full attention and to preclude her analyzing the statements made, she was told:

1. I am positive you have forgotten completely a task I had you do a while back.
2. I want you to work on the full assumption that you did it, even though you can't remember doing it.
3. I want you to recover as systematically as you can the memories of what you did.
4. It was an unexpected task for which you could make no plans to remember. Hence, you forgot it.
5. This task was done between the time of the last interview you remember and this present moment. (Projected time.)

The task was then described to her as regressing in age and recovering a variety of memories about her father, all of which she had now forgotten.

The proposal was offered that she now try to recall what she might have discovered in that age regression by whatever means she chose, crystal-gazing, automatic writing, flashes of memory, or any other means she wished.

She hesitatingly suggested crystal-gazing. Immediately the suggestion was offered that in a series of crystal balls she would see herself at descending age levels until she saw

herself as an infant-in-arms. (As for Patient A, these crystal balls were "fixed.") She was to study these portrayals carefully, until she felt certain that she had "rediscovered" the forgotten memories.

For half an hour she sat silently, absorbed in this task. Finally she turned to the writer and indicated that she was through. Instructing her to keep the memories and to report them in any way she wished, the crystal balls were removed by suggestion. (The reason for this was to prevent her from developing tangential interests by observing again the crystal balls.)

She was asked what she thought about the experience. Her reply was the startling request that the writer examine the back of her right knee.

That examination revealed an old, small, jagged scar. Told about this, she explained, "I saw myself as a little girl. I was six years old. I was playing. I was running backward. I tripped over the root of a tree. My leg hurt. I got up crying. Then a lot of blood ran down my leg. I was scared. Then the crystal ball disappeared."

After some moments of silent thought, she continued, "I'm all mixed up. I think different ways about time. I don't like it. I think you better straighten my mind out and tell me to remember everything. I think I'm in a mixed-up trance. Wake me up."

She was reoriented and awakened with instructions for full recollection of memories.

Soberly she began, "I saw me fall. I've got the scar. You found it. I don't remember it. I just saw it in the crystal ball. Maybe the other things are true, too."

"First I'll tell you and then I'll tell my mother. Then I'll know. This is what I saw: I could say 'Daddy.' My father was holding me. He seemed to be awful tall. He was smiling. He had a funny looking tooth, a front tooth. His eyes were blue. His hair was curly. And it looked yellowish. Now I'm going home and tell my mother."

The next day she reported, "They were real memories. It shocked Mother. When I got home, I told her, 'I've found out what my father looked like. He was tall, blue-eyed (she and her mother were brown-eyed and five feet three inches tall), and curly-haired. It was almost yellow and he had a gold front tooth.' Mother was frightened. She wanted to know how I found him. So I told her about what we did. After awhile she said, 'Yes, your father was six feet tall, blue-eyed, yellowish-red curly hair, and he had a gold tooth. He left me when you were 11 months old. I'll tell you anything else you want to know now, and then let's not talk about it anymore. I know nothing about him at the present."'

However, the patient's curiosity was satisfied. She was used subsequently for experimental work. Although she was given opportunities over a year's time to manifest further concern about her original problem, she seemed to have lost all interest in it.

PATIENT D

This case history centers around an impasse reached during therapy and the utilization of a fantasy about the future to secure an effective resumption of therapeutic progress.

The patient suffered from a profound anxiety neurosis with severe depressive and withdrawal reactions and marked dependency patterns. A great deal of hypnotherapy had been done and her early response was good. However, as therapy continued, she became increasingly negative and resistive.

Finally, the situation became one in which she limited herself, during the therapeutic hour, to an intellectual appraisal of her problems and her needs, while rigidly maintaining the status quo at all other times.

A few examples will suffice to illustrate her behavior. For cogent reasons she could not tolerate her parental home situation, but she persisted in remaining in it despite actual difficulties and in the face of favorable opportunities to leave. She resented her employment situation bitterly, but she refused to accept a promotion actually available. She recognized fully her need for social activities, but she avoided, often with difficulty, all opportunities. She discussed at length her interest in reading and the long hours she spent in her room futilely wishing for something to read, but she refused to enter the library she passed twice daily, despite numerous promises to herself.

Additionally, she became increasingly demanding that the writer must, perforce, take definitive action to compel her to do those things she recognized as necessary and proper but which she could not bring herself to do.

After many futile hours she finally centered her wishful thinking upon the idea that, if she could achieve even one of the desired things, she would then have the impetus and firmness of intention to achieve the others.

After she had emphasized and reemphasized this statement, it was accepted at face value.

She was then immediately hypnotized deeply and, in the somnambulistic state, instructed to see a whole series of crystal balls. In each of these would be depicted a significant experience in her life. These she was to study, making comparisons, drawing contrasts, and noting the continuity of various elements from one age level to another. Out of this study would slowly emerge a constellation of ideas which would be formulated without her awareness. This formulation would become manifest to her through another and larger crystal ball in which she would see herself depicted pleasantly, happily, and desirably in some future activity.

She spent approximately an hour absorbedly studying the various hallucinatory scenes, now and then glancing about the office as if looking for the other crystal ball. Finally she located it and thereupon gave all of her attention to it, describing the hallucinated scene to the writer with avid interest.

It was the depiction of a wedding scene, that of a lifelong family friend, which in actuality was not to take place for more than three months. She saw frequent "close-ups" of herself and of the others. She described the wedding ceremony, the reception, and the dance that followed. She was particularly interested in the dress her image was wearing but could only describe it as "beautiful." She watched the dancing, identified some of the men with whom she danced, and named the one who asked her for a date. Over and over she commented on how happy she looked, and what a contrast there was between her appearance now and her appearance at the wedding.

It was difficult to get her to cease watching the scene of the wedding party, since she was so interested in it and because she was so pleased by her behavior in it.

Finally, she was instructed to keep all that she had seen in her unconscious and to have a waking amnesia for the trance experiences. Furthermore, it was explained, it would constitute a tremendous motivating force by which all of her understandings could be utilized constructively. She was then awakened and dismissed with a posthypnotic suggestion for continuance of the amnesia.

There were only two more therapeutic interviews, and both of these were limited in scope by the patient. Each time she stated that she had nothing to say until she had been hypnotized. Once this was done, she stated both times that she wanted instructions to remember in her unconscious very clearly all that she had seen and thought and felt as she watched the wedding scene. The desired instructions were given each time, and after about half an hour of silent thoughtfulness in the trance state she asked to be awakened and dismissed. At the second visit she terminated therapy.

She was not seen until several days after the wedding, three months later.

Then she entered the office without an appointment and explained, "I've come to tell you about Nadine's wedding. I have an odd feeling that you know all about it and yet don't know a thing. But I do know that I have to give you an explanation for some reason."

Her explanation was that she and Nadine and the bridegroom had been lifelong friends and that their families were intimate friends. Some three months ago, following a therapeutic session, she had felt impelled to discontinue therapy and to devote her energies to getting ready for that wedding. When she was asked to be a bridesmaid, she decided to make her own dress. This had made it necessary to get promoted at work so that she would have better hours. Additionally, she had taken an apartment in town so that she would not lose a total of three hours going back and forth from work. She had gone on shopping tours with various friends to help select wedding presents, and she had arranged for "showers" for the bride-to-be. All in all she had been exceedingly and happily busy.

She described the wedding scene, the reception, and the dance. She was decidedly startled when the writer asked if she had danced with Ed and if he were the one who asked her for a date. She answered in considerable bewilderment that she could not

understand, since she had not mentioned his name, how the writer could ask such a specific question. However, she had danced with Ed but had forestalled his request for a date since she considered him not to be up to her standard. However, she had accepted a date from another dancing partner.

Finally, she was reminded of her original purpose in seeing the writer. Her reply was simply, "I was a pretty sick girl when I first came to see you; I was horribly mixed up, and I'm grateful to you for getting me straightened out in time so that I could get ready for the wedding." She had no awareness that her preparations for the wedding constituted her recovery.

She has been seen occasionally since then on a casual basis. She is happily married and the mother of three children.

PATIENT E

In this case history the patient was not interested in therapy and did not know that she needed therapy, but she was interested in hypnosis as a personal experience that might be enjoyed. Very early in hypnotizing her the realization was reached that, despite her seemingly good adjustment, therapy was seriously indicated.

She was a 19-year-old student nurse of good intelligence, pretty, vivacious, likable, but annoyingly flippant in her general attitudes. She proved to be an excellent somnambulistic subject and interested in experimental hypnotic work. However, it was soon discovered that she had a mild avoidance phobia for water fountains and flower vases. Hypnotic exploration of this rapidly disclosed other items of psychopathology, which she confirmed in the waking state. Among these were the following:

1. She had learned to swim well when she was about 10 years old. However, for some unknown reason she had not been able to swim for at least the last five years. Yet, each season she would go to the lake to swim, don her bathing suit, and walk expectantly down to the shore. As her feet touched the water, she would turn and run away screaming, as a result of a sudden, unexpected impulse. Several hundred feet away she would gain control of herself and embarrassedly walk back to the shore, fully expecting to swim, but only repeating her previous uncontrollable impulsive behavior. Yet each time it occurred, she did not believe it would happen again.
2. She would accept an invitation to go to the theater with some young man. Once inside, she would slip away from her escort and then leave by a side entrance and go home alone. Or if she went to dinner, she would, at the close of the meal, excuse herself to go to the rest room and either wait it out there until her escort left in disgust or she would depart by a back door.
3. Her attitude toward marriage as a possibility for herself was one of bitter intolerance. So intense was her hostility on this topic that she would not discuss it except to declare that this was her "normal" feeling and that she had no particular reason for disparaging marriage so completely.

4. There were a number of other items of psychopathology, but these were not discovered until after therapy had been accomplished.

When the question of therapy was raised with her, she agreed to it provided the therapy were limited to the correction of her swimming problem. She did not realize that therapy in that regard might correct other maladjustments.

Treatment was initiated by training her fully as a hypnotic subject. This she enjoyed, but she was really interested in therapy. Age regression was employed extensively with her, and a series of traumatic, deeply repressed memories were recovered and the experiences relived by her.

Some of these were as follows:

1. When she was about five years old, she and her two-year-old sister were playing about a washtub full of water, while the mother was out of the room. The sister fell into the tub, and the patient struggled to pull her out while screaming for her mother. When the mother came, she rescued the baby, who had "turned blue," and finally spanked the patient most severely "for pushing sister in the water."
2. At about the same period the sister, while sitting in the high chair at the table, managed to tip herself over. The patient rushed across the room with arms outstretched to rescue her. She arrived too late and just as her mother entered to see the patient's outstretched arms and the toppling chair. Again she was severely punished.
3. When she was about six years old, a neighbor volunteered to teach her to swim. This neighbor believed that a child's fear of water is best cured by complete immersion. The patient became extremely frightened, fought, screamed, and bit. Her "misbehavior" resulted in another spanking.
4. At about this same age a neighbor died and the patient was sent to the grandmother's house while the mother attended the funeral. That night the patient returned home and was awakened by her father's coughing (he was bedridden and slowly dying of pulmonary tuberculosis). Distressed by the coughing, she aroused her mother and explained that she wished her father would die. Without seeking the patient's reasons for this wish (when people die, you go to Grandmother's and get cookies and candy, and Daddy likes cookies and candy, so why can't he die and go to Grandma's?), the mother punished her severely.
5. When she was about eight years old, contrary to her mother's orders, she tried to cross a creek on a fallen log used as a footbridge. She slipped, fell, and saved herself by embracing the log. After much screaming on her part, she was finally rescued by her older brother, who subsequently intimidated her by threats of reporting the escapade.
6. When she was about 12 years old, she and her sister, both having learned to swim well two years previously, went swimming. The water was cold and the sister became cyanotic but refused to leave the water despite the patient's frantic pleading and crying.

7. Because of the above experience, she had later refused to go swimming with her sister and brother. He had forcibly dragged her into the water. She fought him so furiously that they "both nearly drowned." She could not remember ever again swimming.

Although the patient relived these various experiences with vivid emotional intensity in the trance state, she protested that they had been forgotten events. Therefore, they ought to remain forgotten, and she declared emphatically that she would not remember them when she awakened.

Furthermore, she demanded that the writer begin therapy on her swimming problem immediately, doing this in a "subtle" way so that she would not suffer any more emotional stress. Efforts to correct her attitude while she was still in the trance were futile, as proved to be the case when she was awakened.

At the next interview the patient was definitely hostile. She declared that she had lost her interest in experimental hypnosis; she was interested in prompt and immediate correction of her "swimming problem and nothing more." In the trance state she confirmed this attitude but was much less hostile. She also declared that she did not want to remember consciously any of the memories previously recovered in hypnosis, since they had "once been forgotten and might as well stay that way."

Accordingly, her demand was accepted, and she was assured that all efforts would now be directed as she wished.

She was then disoriented for time and reoriented approximately three weeks into the future. Immediately she was told that, since therapy had been terminated the first part of June and it was now the latter part, one thing remained to be done. This task was that of "putting into effect the therapy that had been done." The opportunity to do this, in fact, was rapidly approaching. Her vacation would occur in the latter part of July and the first part of August. Therefore, it would be well to plan how to utilize that vacation to establish her therapeutic gains on a reality basis.

Thereupon, collaboratively, she and the writer devised the following plan. She would spend the vacation at a summer home on a lake well known to her. She was to purchase a new bathing suit and a small waterproof silk bag large enough to hold a package of cigarettes and matches. This bag would be carefully attached to her bathing suit for the first two days, if necessary, but would probably be dispensed with in much less time.

The cigarettes and matches would now be presented to her, a package of Lucky Strikes [Ordinarily she refused to smoke other than her own particular brand of cigarettes.] on which the writer would, in her presence, inscribe, "This really is a lucky strike." These she would now put into her handbag with the matches slipped into the cellophane wrapper, and she would keep them hidden from her conscious mind until the time came to use them.

At the lake, and in the form of posthypnotic behavior, she would attach the waterproof bag containing the cigarettes and matches to her bathing suit. Then, consciously, she was to stroll down to the beach, speculating about sitting on the raft and wondering whether she would sit facing out over the lake or facing the shore.

Once on the raft she would experience an overwhelming desire for a cigarette. While wishing for one and dangling her feet in the water, she would "accidentally" discover the waterproof bag and explore the contents. She would be so delighted that she would immediately light a cigarette and only while puffing it would she begin to wonder where they came from. Examination of the package would lead to the discovery of the writing on it. While she pondered its meaning, she would finish the cigarette, toss the butt into the water, and strike out for shore, still puzzled about the inscription.

Upon reaching shore, she would realize that she had left the cigarettes on the raft, and she would turn and strike out for the raft again. Upon arriving at the raft, she would be hungry for another cigarette and would smoke again.

As she smoked, she would suddenly remember completely everything that had happened since she had donned her bathing suit.

The patient listened attentively to these elaborate instructions and comprehended readily what she was to do. Then, while she was still in the trance state, she was "disoriented" for "the latter part of June" and projected in time to September in the situation of entering the office.

She was asked, "Well, what really happened on your vacation?"

Her narrative was essentially as follows:

> When I started to get undressed to put on my suit, I had an awful time. I was so absentminded. Then, when I went down to the beach, I was wondering why nobody was on the raft, and I decided to sit on it. The next thing I was ravenous for a cigarette. Then everything happened just as you said last June. I smoked a cigarette and struck out for shore, but then I had to go back and get my cigarettes. And then I started to remember everything about undressing and getting that silk bag fastened to my suit and thinking about the raft and swimming out there twice. And then I knew I was over my swimming problem and I really enjoyed swimming every day.
>
> Now I'm back at work and everything is swell.

She was reoriented to the current time and emphatically instructed to obey, to the last detail, all instructions that she had ever, at any time, been given when in a trance state. With equal emphasis she was instructed to keep all unconscious knowledge from her conscious mind. This must absolutely be done until such time, if it ever did occur, that both she and the writer independently would approve of her conscious awareness of

things unconscious. This instruction, in accord with her previously expressed attitude, she accepted most readily.

She was awakened and dismissed. The cigarettes and matches had been carefully wrapped in tissue and concealed in her handbag.

She was seen again in September. She entered the office with a merry laugh and declared:

> Well, you already know everything that happened on my vacation. It all happened just as you said. By the end of my vacation I got so puzzled by everything that I sat down one day and deliberately remembered everything. It was so confusing because I started with the appointment I had with you in the first part of June. I really had a lot of trouble getting straight about "the last part of June," and then "September," and making them both fit into the real time. Puzzling that out was a job, but I got it straight. You ought to try to think a thing out like that. At first, the last part of June and September were just as real as any other memories. I knew they couldn't be so, but they were real and it was a terrific job, but exciting and interesting.
>
> But when I got them straightened out, I could see them as ideas that I had for the future, and then I was straight in my mind. That's when the real merry-go-round started. That's when I started to remember everything that happened since you began to work with me—all those things you dug out of me. If you had as much fun digging them out as I had remembering them and putting them together to make sense, I won't have to apologize for being so stubborn.
>
> The whole thing went pretty fast. I puzzled all morning one day, and then after lunch I really sat down and started my think-trap going, and by dinnertime I had everything straight.
>
> That first September report wasn't right in some things. What really happened started in June, after that trance that really started things. I started getting ready for my vacation, and the first thing I had to do was to get a bathing suit. I was looking for a special suit, but I didn't realize it then. I didn't know it was blue.
>
> Then I had a job finding a waterproof silk bag to send overseas to someone—I hadn't really made up my mind who, so I couldn't send it after I got it. Then I misplaced my handbag. Every time I found it again, it got misplaced again. The last place I found it was in the suitcase I took to the lake. I can remember now all the tricks my unconscious played on me to keep those cigarettes hidden from my conscious mind.
>
> Well, the rest at the lake was like you said, except that when I was hanging my feet in the water on the raft, I kept worrying about the toenail polish coming off. But the rest was like you said. But I kept wondering what happened to me because I was enjoying the swimming.

But that isn't all. After I remembered all those other things you dug out, I knew I could handle them, but I didn't know what I was going to do. I had to wait till I got home.

I'll tell you them now, all except one. I'll tell you that next time.

She continued:

For years and years I have wanted to take a hot soak in the bathtub. I always filled the tub full and then I would step in, pull out the plug, and take a shower. It always made me so mad, but I did it every time. And if there wasn't a shower, I'd just stand in the tub and sponge myself. Now I can take a tub bath.

Another thing! I can drive a car now. I had to give it up because I got in the habit of shutting my eyes and speeding up, sometimes in the city, sometimes in the country. Remember the footbridge well, I always did that to cross bridges, but I just realized that up at the lake. Now I don't shut my eyes to drive over a bridge.

Those poor guys that dated me and took me out! That neighbor that took me out in the water and wouldn't let me come back and ducked me. Well, I let those poor fellows take me out and I made sure I got back.

And Sis and the high chair! You couldn't hire me to stay in a place where there was a baby in a high chair. Some of the nurses invited me to their homes for dinner, and after I got in the house I just walked out. I didn't know why then. Now I can visit people who have babies in high chairs.

And Sis getting blue when she was a baby and then when we went swimming that time. I've never worn anything blue because of that, and it's becoming to me. First the blue bathing suit and now this new outfit I've got on.

And I've joined the church. I always wanted to go but couldn't stand being in a church. I even took my training in a Catholic hospital because I'm a Protestant and I wanted to be sure to keep away from church. But just because they have funerals in church doesn't stop me. There are a lot of other little things, but you get the general idea. What I don't understand is how I kept all this in my unconscious and made everything so tough for me. How can a person be so stupid and so stubborn? But I suppose you're going to call me stubborn now because I'm not going to tell you the most important thing that happened. But I'm not really stubborn because I've got a good reason this time, and I'm going to tell you the next time I see you.

She was not seen again until mid-October. As she entered the office, she said:

> I'm ready to tell you, but first I've got to explain a little. Mother had it awful hard when we were kids—looking after us, taking care of Father, earning a living for us. I thought that marriage was horrible, just trouble and work and heartache, and that husbands were always sick. I just never straightened out that idea. So last month I visited Mother and had a long talk with her. I didn't tell her those things you dug up out of my unconscious; we just talked about when the kids were little and my father was sick. She really loved Father, and she doesn't think she had it so hard. I wish I'd had enough sense to get her ideas before, instead of keeping my kid ideas in my unconscious. So I told her about Joe, how we're going steady since I got back from vacation. She was very pleased when I told her I was going to get married some time next year. She never did like nursing for me, and now I wonder why I took it up—my father, I suppose. But now I want a home and kids and a husband. So now I'll introduce you to Joe—he's waiting outside.

The young people were seen casually on several occasions before their marriage. When their first child was about a year old, a visit was made to them, and at this time the mother was met.

During the course of that visit the mother, who knew that her daughter had been the writer's patient and had been hypnotized, expressed an interest in being hypnotized also. Immediately the daughter was asked if she had ever given any account of her hypnotic experiences to the mother. This was disclaimed.

The mother proved to be an unusually good subject and responded readily to age regression. She was regressed to the time, "when your daughter was between four and a half and six years old, at which time something may have occurred that frightened you and her very much."

Among the things elicited was a similar account of the washtub episode. The patient's age was given "as almost two months past her birthday." Similarly, a comparable account was obtained of the high chair episode. The patient was then about five years and nine months old.

The swimming lesson by the neighbor and the funeral episode were both adequately confirmed, including the midnight spanking for the "death wish."

The fallen log footbridge episode apparently was not known to the mother, but she did relive an episode, when asked to be sure to speak to her daughter about something on the west side of the house, of anxiously cautioning the patient "never, never walk on that tree that fell across the creek in that bad windstorm."

The mother was awakened with instructions to remember fully what had happened in the trance. She was tremendously startled by the recovery of these memories, and she, her daughter, and the writer spent a considerable period of time discussing those past experiences. The mother showed good capacity to understand, and she was relieved to know that the "death wish" was something entirely different.

Some months later the mother was seen again. The purpose of her visit was to find out if there were any other things that she had done that she ought to talk over with her daughter. She was hypnotized and told that she could remember freely and comfortably and discuss anything of actual interest to her daughter whenever the occasion arose.

A social telephone call from the daughter some months later disclosed that the two of them had been reminiscing happily and contentedly and that she had a very pleasing recollection of her childhood.

The patient's adjustments have remained good. Her relationship with her mother has continued to be happy, and she is very much interested and contented with the raising of her two children.

GENERAL COMMENT

Perhaps the first discussion of these therapeutic experimental procedures should concern how fantasied accomplishments could have proved such effective measures of therapy. We all know, from common experience, how easy it is to fantasy great deeds, and how far short fall the endeavors in reality. The fantasied story is such a masterpiece until it is set on paper, and the beautiful painting, so clearly visualized in the mind's eye, becomes a daub when the brush is applied to the canvas. However, it must be borne in mind that *such fantasies as these are conscious fantasies*. Thus, they represent accomplishments apart from reality, complete in themselves, and expressive, recognizedly so to the person, of no more than conscious, hopeful, wishful thinking.

Unconscious fantasies, however, belong to another category of psychological functioning. They are not accomplishments complete in themselves, nor are they apart from reality. Rather, they are psychological constructs in various degrees of formulation, for which the unconscious stands ready, or is actually awaiting an opportunity, to make a part of reality. They are not significant merely of *wishful desire* but rather of *actual intention* at the opportune time. Thus, one can endeavor to record a fantasied story on paper, but its merit may derive from the "sudden flashes of inspiration that come unbidden to the mind." Or an author may consciously endeavor to write a novel and find that his characters "do not behave but run away" with him.

In these case histories extensive emphasis was placed upon fantasies concerning the future, and every effort was made to keep them unconscious by prohibitive and inhibitive suggestions. . By so doing, each patient's unconscious was provided with a wealth of formulated ideas unknown to the conscious mind. Then, in response to the innate needs and desires of the total personality, the unconscious could utilize those ideas by translating them into realities of daily life as spontaneous responsive behavior in opportune situations.

An experimental illustration of this may be cited. A normal hypnotic subject who disliked ostentatious display of learning and who spoke only English was taught in a deep trance

to recite “Die Lorelei.” This was done as a seeming part of an experiment on memory that was being completed and without informing him that he was learning a poem or that it was in German. A posthypnotic amnesia for this task was then suggested.

About two weeks later at a social gathering, through prearrangement, a colleague of the writer’s offered to entertain the group by singing and reciting variously in Polish, Austrian, Italian, French, and Spanish. After listening with increasing displeasure, the subject remarked, “I can talk in nonsense syllables, too,” and proceeded to recite “Die Lorelei.” To his full conscious understanding, the subject’s utterances were no more than nonsense syllables spontaneously offered in the immediate situation. Rehypnosis was necessary to convince him otherwise.

This experiment differs from the case histories in that future possibilities in a life situation were not a part of the experimental situation. Rather, the subject’s unconscious was provided with special learning, and then, later, an opportunity was created in which that special learning could become manifest in response to inner personal needs.

For the patients, special understandings for the future were developed in their unconscious minds, and their actual life situations presented the reality opportunities to utilize those ideas in responsive behavior in accord with their inner needs and desires.

The fashion in which the patients made their fantasies a part of their reality life was in keeping with the ordinary natural evolution of spontaneous behavior responses to reality. It was not in compliance with therapeutic suggestions, nor did it seem to derive even indirectly from anything other than the patients’ responses to their realities. Furthermore, their behavior was experienced by them as arising within them and in relation to their needs in their immediate life situation.

Thus, Patient A vaguely wondered about his next appointment with the writer and acted on a sudden impulse to ask for a raise in salary, which, in turn, led to a series of events. Patient D did not leave the parental home for the cogent reasons she had discussed with the writer but because she wanted to make a dress she wished to wear. And Patient E responded to her fantasies by searching blindly for a bathing suit that met unconscious needs related to her distant past. So it was with the other two patients.

The kind of fantasies by which the patients achieved their goals is of marked interest and significance. They were not of the elaborate, grandiose type that one commonly has when fantasying consciously about one’s wishes. They were fantasies in keeping with their understandings of actually attainable goals. For example, Patient A was pitifully modest in wishing for “just fair” health. Nor did he think of winning a fight, but hoped to be able to “take a licking like a man.” Patient B’s thinking did not center around visions of receiving one promotion after another but dealt with the humdrum realities of packing and moving. Patient C validated her fantasies in terms of a reality scar, and her father was just a man with a “funny-looking tooth.” And Patient D saw herself in her fantasy not as a star in the entertainment world but as a happy guest at a friend’s wedding.

So it was with all the fantasies about the future experienced by these patients. There was no running away of the imagination, but a serious appraisal in fantasy form of reality possibilities in keeping with their understandings of themselves.

To speculate upon the question of why and how "time projection" proved to be an effective therapeutic measure for these patients is difficult. One can hardly do more than to draw parallels with experiences common in everyday life. For example, advertising and salesmanship extensively utilize appeals that stimulate fantasies of the future. An example more closely comparable to the above case reports is that of writing, after much indecision, a letter accepting a new position. Once it has been written, even though not yet mailed, there develops immediately a profound feeling that the die has been irrevocably cast. There results then a new psychological orientation of compelling force, effecting a new organization of thinking and planning. The writing of the letter constituted an initiation of action, and, as was mentioned earlier, an action once initiated tends to continue.

For these patients, apparently, the establishment of a dissociated state, in which they could feel and believe that they had achieved certain things of benefit to them, gave to them a profound feeling of accomplished realities which, in turn, resulted in the desired therapeutic reorientation.

---

[1]Essentially, this is a simple though detailed technique of suggestions by which the deeply hypnotized subject is reminded of the current date; told that the seconds, minutes, and hours are passing; that tomorrow is approaching, is here, and now is yesterday; and that as the days pass, this week will soon be over and then all too soon next month will be this month. Particular attention must be given, in using this technique, to be most accurate in verbalizing the transition from the future to the present to the past, and to do it easily and gradually without rushing the subject.

[2]The date for the patient, as a consequence of preceding waking and trance discussions, would necessarily be several months in the future. Such future dates are best selected by the subject, since the hypnotist might choose one inauspicious for the situation. Also, the selected period of time should not be too exactly defined. For example, if an actual future date, such as the next birthday, is desired, the orientation should be to "some days before your next birthday." Then it becomes a simple matter to let the subject define the date progressively more exactly. When the actual future date is unknown, having the subject glance out of the window and describe what he sees may indirectly reveal the time of day, the season of the year, and the location. Thus, one subject described the noonday Christmas shopping rush in a distant city.

[3]Constant alertness must be exercised to prevent any undue thinking that might break down the established psychological orientation.

[4]Therapeutically there was no reason for the patient to think otherwise. In final analysis the outcome did derive from the opportunity for a new job.

Facilitating Objective Thinking and New Frames of Reference with Pseudo-Orientation in Time

Milton H. Erickson

Unpublished manuscript, circa 1940s.

Note: This study was never published, but the fragmentary notes on the cases presented at the end of this paper are part of the clinical data the author was collecting for it. The paper mentioned, "Unconscious Insights" is indicative of the author's interests and initial hypnotherapeutic orientation at that time.

A common, repetitious learning of everyday life is the frequent, marked discrepancy between anticipation and realization. The value and significance of hopes and wishes, upon becoming realized, so often prove to be quite different from what was originally expected. This is particularly true in situations centering around emotional problems. There is a natural tendency to overemphasize the importance of immediate understandings and subjective attitudes in preference to a thoughtful, objective consideration of eventual probabilities and possibilities.

This common experience of daily life has been utilized extensively by this author for many years as the basis for a special therapeutic technique in the handling of a wide variety of emotional problems that have been experienced by the patient as too difficult to evaluate satisfactorily. In essence, this technique is not new—the author has published previously on experimental therapeutic methods employing basically similar principles. Its central feature is the instruction of the patient, hypnotized and pseudo-oriented in time, to view the problem for which therapy is being sought as one deriving from the remote, recent, or immediate past, the current situation, or the impending near or remote future. In this way the pressing emotional urgency of the actual current situation can be altered by the interjection or interpolation of a sense of perspective in time, thereby creating an opportunity conducive to more comprehensive and objective thinking. In this regard, one need only call to mind such familiar plaintive utterances as: "I knew all the facts even then, and I should have foreseen this outcome; if only I could do it all over, I'd do the same things but for entirely different reasons and with such different results." And, "If only I could have known for sure, or just had the feeling that it was going to happen, I could have changed my feeling so easily."

This comprehensive, objective viewing of stressful matters is thus carried out against suggested backgrounds of various possible understandings. Ideally, objective thinking is possible in the ordinary waking state, but emotional stress is likely to constitute a serious interference, if not an actual barrier. In contrast to the functioning of the ordinary state of conscious awareness, hypnosis permits a dissociation of ideas and attitudes in one relationship and a vivification and intensification of others in another relationship, thereby facilitating a much more effective examination, identification, and evaluation of

wishes, fears, beliefs, and understandings. In this way clear comparison of intrinsic values, a resolution of conflicts, and an integration of understandings can be more readily effectuated.

This technique was in part developed from an experimental therapeutic study conducted in the early 1930s and published under the title "Unconscious Insights." It is also essentially a narration of the technique described in "Pseudo-orientation in time as a hypnotherapeutic procedure" (Erickson, 1954). The actual procedure is rather simple. Upon inducing a medium or deep trance, suggestions are offered to effect a dissociation from the immediate environment and then to emphasize the unimportance of the identity of the day of the week and then of the month, culminating in an amnesia for time, place, and situation, but with an awareness of the general identity of the self.

Clinical Data (Fragmentary Notes)

Edward and Jean: A childless couple, content to be childless. His mother lived with them, dominating the household completely. Jean finally rebelled and gave Edward his choice between kicking his mother out or divorce. Edward sought counsel.

Techniques of unconscious insights employed in both directions. His discovery of a desire for paternity. The ejection of his mother. Reconciliation. Two children.

Walter and Willa: Incessant quarreling for six years, with threats and counter threats of divorce. Weekly visits by her parents. Weekly dinners at her parents' home. Walter finally rebelled and "laid it on the line." Willa seen as patient. Solution: Weaning from the parents and several additional pregnancies.

Howard and Margaret: Children grown. No desire for further family. She was only 35. Both decided on a vasectomy and both came for counseling. Her unconscious fears of his infidelity. His unconscious fears of infidelity. Consideration of salpingectomy is rejected. Decision for contraception.

Marie and Ralph: His infidelity. Guilt and confession. Her desire for revenge. Her request for counsel and her own discovery of a profound sense of guilt.

Dr. B: Sought counsel concerning vasectomy. He and his wife were content with one child. They wanted no more. In the trance state he recognized his definite, though unformulated, ideas of infidelity. Also, he discovered serious fears of the consequences and a feeling that a divorce would result.

Without disclosing his fears to his wife, he raised the question of vasectomy vs. salpingectomy. He rejected her offer, rejected his trance learnings, underwent vasectomy, was eventually divorced for the reasons originally feared.

James and Joyce: Ages 23 and 22. Married when she was 16. Four children by the age of 22. Much debate between them regarding vasectomy vs. salpingectomy. Salpingectomy rejected. Vasectomy accepted and counsel sought by both. Both rejected unconscious insights. Divorced three years later.

Charles and Carol: Both aged 25. Both only children. Both resolved to have no children. Both rejected contraception. Sought counsel regarding vasectomy or salpingectomy. Unconscious insights confirmed five years later by several pregnancies.

Albert and Janice: History of 11 miscarriages. Majority between the second and third month. Much bitterness and resentment and depression. Salpingectomy proposed. Consistent rejection in the trance state. Five successful subsequent pregnancies.

Leon: Aged 38. Chronic alcoholism. Wanted to know his future. Unconscious discovery of homicidal attitudes. Twelve years of sobriety.

Joe and Ann: Ann, university graduate. Joe, grade school education. Counsel requested concerning advisability of marriage. Unconscious insights approved.

Jack and Jill: December and May situation. The man's unconscious insights objected.

James and Patricia: The prospective bride requested counsel regarding a premarital sex relationship. Invariably rejected premarital relationships in the trance state.

Phil and Nancy: Marriage counseling for mixed racial marriages and mixed religions.

Self-Exploration in the Hypnotic State

Milton H. Erickson

Quoted from the *Journal of Clinical and Experimental Hypnosis,* 1955, 3, 49-57.

INTRODUCTION

This brief study is reported in detail for a number of reasons. It is an account of a classroom experiment proposed and executed by a medical student as an intellectual project for classroom purposes. Actually, it was an unconscious seeking by the student for specific psychotherapy in the guise of an intellectual effort.

The fashion in which the proposed task was to be done, apparently to illuminate the intellectual aspects, served in reality to define the manner in which the student wished unknowingly to achieve his therapy.

While every effort was made to avoid giving the student assistance, other than that of creating a favorable situation, various suggestions were nevertheless seized upon by him to develop his task.

The results obtained by the student serve to illustrate with remarkable clarity:

1. The obvious but unrecognized unconscious motivations and needs served
2. The separateness of unconscious and conscious memories
3. The actual possibility of dissociating the affective and the cognitive elements of a traumatic experience
4. The process of the transfer of memories from the unconscious to the conscious mind
5. The extensive effects of a single, deeply repressed traumatic experience upon the personality and the comprehensive changes achieved upon its reintegration into the experiential life of the person
6. The numerous minor clues, given during the task performance, highly informative of the significances involved

STATEMENT OF EXPERIMENTAL PROBLEM

One of a group of medical students being trained in hypnosis had shown an almost compulsive-obsessional interest in psychiatry and had studied avidly on the subject. He early volunteered to be a hypnotic subject for the group but had placed a restriction on his role as a subject by declaring that no intimate or personal questions be put to him. He proved to be easily trained and most capable of developing complex hypnotic phenomena.

After some weeks work with the group, at the beginning of one session this student announced his wish to raise a special question for the evening's work and discussion. This question he

explained as follows: People normally forget many things and hence do not know that they have forgotten them. These things may be only of past significance, or they may be of actual present but unknown and unrecognized significance. They may be of a minor or a major character and importance. And they may be of a traumatic or a nontraumatic nature.

Therefore, would it be possible for a person to set himself the task of remembering some definite but actually long-forgotten event and to recall it vividly and comprehensively?

The reply was made that this question was worth investigation and that he could retire to the next room for half an hour and really work on recovering some completely forgotten memory of his own. He replied that he had been thinking about the question off and on for the past week without formulating any ideas, but he would be glad to devote an intensive half-hour to the subject.

During his absence the question was discussed with the other students. At the expiration of half an hour he was summoned. He explained sheepishly that the task of attempting to remember something that was completely forgotten and that had occurred at a time and in a situation that could not be recalled was as futile a task as trying to describe some totally unknown place. He had, however, recalled many things, but these were not forgotten things, but merely things he had not thought about for varying lengths of time.

The suggestion was offered that he *might* spend the next half-hour endeavoring to recover a forgotten memory of something that had occurred previous to his tenth year and about which he had not even thought for at least 15 years. (All emphasis in this suggestion was placed upon the word might, thereby rendering it a permissive suggestion, offering only a general concept of possible time periods.)

Half an hour later he reported that the task was even more hopeless than ever. He had recalled innumerable things, but they were memories about which he had had no occasion to think, and they did not constitute recoveries of forgotten things. He then raised the question of whether or not he could be given the same task in a hypnotic trance. He was answered that he could be given the task, but he would have to discover for himself whether or not he could perform it. He agreed to that stipulation.

He was hypnotized deeply and instructed to review mentally his question and his two half-hour efforts and to spend at least 10 minutes considering the feasibility of the task.

After 10 minutes he stated that the entire problem still looked hopeless to him.

Still maintained in the trance state, he was asked if he wanted any help or guidance, and he replied that any assistance would vitiate the purpose of the effort, since such assistance would direct and aid in memory recovery, and it was his desire to see if such a memory recovery could be effected by a person in either the waking or the trance state and accomplished solely by personal efforts in mental searching.

He was told that he would be given no aid but that certain general remarks could be made to him which would give him more opportunity to do the task. Hesitantly he agreed to hear the remarks, but upon hearing them, he accepted them readily. These remarks were offered to explain the following matters. Since he was in a somnambulistic trance and usually manifested catalepsy, it

would serve no purpose either to maintain or abolish catalepsy, which was only an incidental part of his trance state and not an integral part of the proposed task.

Therefore, in performing his task, no incidental item of behavior such as catalepsy should be permitted to interfere with his efforts. Also, since he usually kept his eyes open in the trance state, that behavior item should be regarded in the same manner as the catalepsy.

Since he would be doing his task in the presence of the group, he should recognize it as solely his task in which nobody else had a part; it would be well to limit himself to his task without including any member of the group by any response of any sort. In other words, he was essentially to isolate himself from the group.

Inasmuch as the forgotten memory belonged to him, it should not be shared in any way until he had an opportunity to consider that sharing as a distinctly separate problem. Hence, his task should be a mental performance reoccurring within himself. Additionally, it would be necessary for him to keep in mind that, for example, when the task was done, it would be desirable for him to establish contact with the writer to give instructions about awakening him, or for any other contingency that might arise. Then, too, he might want instructions about what to do with whatever results he secured. Therefore, he could, at any needful time, address inquiries or remarks to the writer.

After these remarks had been repeated to him to enable him to think them over thoroughly, he asked, "How do I start?" The reply was cautiously given, "It is your task. You will start by waiting until I announce the time and as soon as I do, you will begin in your own way."

While waiting for the time announcement, he stated, "I'm going to look for a forgotten thing just as I said before. It should be something like you said that maybe happened before I was 10, and it should be something I haven't even thought about for at least 15 years. I think that is a reasonable problem."

THE EXPERIMENTAL PROCEDURE AND RESULTS

The time of 7:30 P.M. was announced. He settled himself in a chair, still in a deep trance, bowed his head, and closed his eyes.

At *7:50* P.M. he called, "Dr. Erickson, I have a feeling that I am getting something, but I don't know what it is. But I am curious." Reply was made, "Thank you for telling me."

About 10 minutes later he asked if it were warm or cold. Reply was made, "I find the temperature comfortable."

About five minutes later he announced, “I’m getting scared, awful scared, but I can’t think of anything." No reply was made.

Within a few minutes he presented a distressing picture of indescribable terror that seriously alarmed the medical students. Falteringly he gasped, “I’m scared, a I'm going to get sick. But I don't know why. Tell me to rest."

He was told, "Stay just where you are in your mind, but rest a few minutes."

Immediately he relaxed and declared, "I am terribly scared, but I can't remember It is the awlfulest feeling. I think I am going to get sick. Don't let me get sick."

He was told, "I do not know what you are doing. Getting sick might be part of it. I will not tell you how to do your task."

To this was added, "Do you want to wake up and rest or just rest in the trance with your gears in neutral, the engine just idling, neither going ahead nor backing up?"

He answered, "Just as I am."

A few minutes later he asked the time, and as it was stated, the look of intense terror reappeared; retching but no vomiting developed. His breathing was labored and spasmodic, his hands clasped and unclasped convulsively, and he seemed about ready to collapse.

Suddenly he gasped, "Rest."

Immediately he was told, "Hang on but rest."

Again he relaxed and declared, "It's too big, I can't do it. Tell me how." He was told, "I can't tell you how, but I can offer a suggestion. You say it's too big. Why not do it a part here, a part there, instead of the whole thing at once, and then put the parts together into the whole big thing?"

He nodded his head, asked the time, and again manifested, as the time was stated, intense emotions of varied types. *Rage, terror, grief, fear, hatred, hysteria, sickness, despair, bravado, shock, horror, agony* were the words written down by the students as they watched him and recorded their interpretations of what they saw manifested by him, and the writer was willing to agree with them.

Finally, a state of what appeared to be stark terror developed. His face was contorted, his hands were tightly clasped, his jaws were clenched, his breathing was labored, his neck muscles were taut, and his body was rigid.

After about two minutes he shuddered, relaxed, sighed, and said, "Rest."

Asked how he wished to rest, he answered, "I've got started. I've got the feelings. I don't know what the memory is. Wake me up and let me rest, and then hypnotize me and just tell me to finish the job. I still got the whole thing to do yet. But I got to rest."

He was awakened with instructions to rest and to have a comprehensive amnesia for what had happened in the trance. He awakened, wiped the perspiration from his face, remarked that he must have eaten something that disagreed with him because he felt sick to his stomach, wandered about the room opening windows, remarking about the heat, and added that he hoped to learn something if the writer would start discussing the question he had propounded. Thereupon he

returned to his chair, sat down, but jumped up and asked one of his classmates what the assignment was in dermatology. Without waiting for an answer, he started a casual conversation with another student.

After about 10 minutes he returned to his chair, sat down, looked expectantly at the writer, and developed a deep somnambulistic trance.

He was told, "You said just before you took your rest, 'I still got the whole thing to do.' The time is now nine o'clock."

He closed his eyes, a look of interest appeared on his face, then one of amusement. Many head movements were made, as if he were looking from side to side. This lasted for a few minutes, and then his head movements became jerky and his hands and arms moved slightly in a jerky fashion. Suddenly a look of anger appeared on his face, followed by a short jerk of his body. Then he stiffened in his chair, his face contorted, his hands clenched, and his biceps contracted. There followed then a tremendous variety of facial expressions as described above, with much jerking of the head from side to side and twisting of his body.

After about 10 minutes of this he slumped exhausted in the chair and gasped, "Rest." Immediately he was told, "Stay where you are in your mind and rest."

He relaxed and declared, "I'm through. I did it. But I don't know what to do now. You got to tell me or I'll forget it all over."

He was answered, "I can give you some suggestions. Listen carefully. I think you have recovered a long-forgotten traumatic memory. [He nodded affirmatively.] You know it now in your unconscious mind. You do not know it in your conscious mind. Keep it fully remembered in your unconscious mind. I will awaken you and let you find out for yourself if you want to know it consciously. Is that all right?"

Since he nodded his head affirmatively, he was told to awaken with only a conscious amnesia and to rest awhile. Then the writer would discuss matters.

He awakened, complained of feeling "horribly washed out," "sick," 'tired," and "like I just took an awful beating."

He added, "I'd swear that someone had just been kicking me around and punching me. My gluteals feel like they've been kicked. And my ribs hurt. I feel as if Joe Louis had given me a workover."

He went out to the water fountain, took a drink, returned, asked the same student about the dermatology assignment, and again did not wait for an answer. He wandered about the room, began and interrupted conversations, and was exceedingly restless.

Finally he sat down and remarked that it was getting very late, that the writer ought to discuss the question he had propounded at the beginning of the evening.

The writer began by summarizing the question he had raised and then went on to state that such a forgotten memory as he proposed to discover would probably be a rather deeply repressed

memory. Hence, there was a good probability that the repression would derive from a traumatic character of the memory. Therefore, recovery of such repressed memory would entail a lot of distress, pain' and actual misery. Furthermore, self-protective tendencies would make such recovery slow and difficult.

With hypnosis there could be a more rapid recovery of the memory, and the self-protective tendencies would be greatly minimized. However, such a recovery would first be limited to the unconscious mind. Then there would arise the question of whether or not the unconscious knowledge could or would be shared with the conscious mind. If it should be, then the person would have to experience mentally the original trauma with all the personal pain that would accompany the recovery of the repressed material.

In his case there would be a number of questions he would have to consider. Would he be conscious? Or would he want to know it consciously? Also, while his willingness to work on such a problem in the presence of his classmates implied his willingness to have them see his behavior in so doing, would he want them to see his conscious reactions to a conscious realization? Then, too, even if he were willing for that, would he want them to know the content of the repressed material?

As for the method of achieving a conscious understanding, there were certain considerations he should have in mind. Would he want the whole thing to irrupt into his conscious mind all at once? Or would prefer to have it come piecemeal, one part at a time, with the possibility of halting the process and mustering his strength so that he could more easily endure the next development? Would he want to separate the affective from the cognitive elements and experience the one or the other first? Or would he like to have the recovery follow the same course of development, the same chronology, as the original experience?

He interrupted to declare that the latter sounded best and to ask when a beginning could be made.

Reply was made, "The other students are here."

Thoughtfully he answered, "I don't care what they see, but I don't want them to know until I know first. We're all medics, so I figure that they ought to be able to take it. But I want the first look. When can we start?"

He was told, "It is now after 10 o'clock. What do you think you have been doing? Why do you feel so tired, so beaten up?"

After a long pause he said, "You mean, I've done that job I talked about when I came, that I know it in my unconscious and that you are waiting for me to figure out if I want to know it consciously? I'm pretty sure that's right—I better think it over. I'm not just beginning the job. I'm on the homestretch and I'm sick. Give me a few minutes."

Shortly he declared, "I'm going to take it just like it really happened. What time is it?"

He was told 10:30.

He smiled and began, "That's funny. A scene just flashed into my mind. It's just as clear as if I were there looking on. I'm back in Oklahoma. Let's see. I'm almost eight years old. And there is

that shirttail cousin of mine. I haven't seen him since I was eight years old. He moved away." Then, in the manner of one who is hallucinating visually a past experience, he continued, "Us kids are playing. We got short pants on and we are having fun." Then in a detached fashion he added, “Nothing traumatic about this. I can see us wrestling and pushing and kicking up in the straw. We are in the cow barn. We are having a whale of a time. Hey, he pushed me. That hurt. I hit him. He hits back. What a fight. Slugging away. Oh no, no, no, no, don't, don't, don't."

At this point he stopped verbalizing, closed his eyes, and shuddered; there followed a duplication of his previous disturbed behavior, with one new addition. Repeatedly he seemed to be endeavoring to speak but unable to do so. For about 20 minutes he was absorbed in the throes of this experience, and finally he collapsed in his chair in exhaustion and said, "Thank God, he will live."

Slowly be straightened up in his chair and remarked, "Yes, he lived, and I forgot the whole thing. I haven't even remembered him. I never dared. I couldn't. I haven't remembered it for years and years-more than 15 years. I just put it out of my mind completely."

After further similar comments he suddenly remarked, "I might as well tell the rest of you what it's all about," and he proceeded to relate the story. In summary, his account was as follows:

One summer day before his eighth birthday he was playing in the cow barn with a distantly related boy of his own age named Johnny. They were wrestling and tussling, and unintentionally they hurt each other. This led to an active fight, and Johnny, smaller than he was getting the worst of the battle. To even the contest, Johnny grabbed a pitchfork and attempted to jab him. In turn, he seized a pitchfork used in cleaning the barn and unfortunately stabbed Johnny in the left calf. When Johnny screamed, he jerked the fork tine out and was even more horrified by the pulsing stream of blood.

Johnny ran screaming and limping to the house, while he turned and ran to the pump and began pumping water frantically into the horse trough.

As he learned later, his father applied a tourniquet and summoned a physician. While waiting for the doctor, the father came to the well and, seizing him, went to the horse trough, sat down, and proceeded to spank him thoroughly, as he lay across his father’s knee, staring at the green scum of algae in the horse trough. Then his father roughly dragged him to the house and made him stand and look at Johnny.

The physician arrived and dressed the wound, then wanted to see the fork. His father cuffed him and sent him to get the fork, which he did in a turmoil of emotion.

After examining the fork, the doctor administered antitetanus serum, explaining the reason. Upon learning this, the father beat his son again.

Just before the doctor left, Johnny developed anaphylactic shock. His eyes swelled shut, his tongue enlarged and protruded from his mouth, and he became a "horrible greenish color.”

He saw the doctor give another injection, which he thought was again antitetanus (afterwards he learned it was "medicine to help Johnny live"), saw the doctor insert a spoon into Johnny’s

mouth (to lessen respiratory embarrassment), and then take out a knife (scalpel) to cut Johnny's throat (do a tracheotomy). He was all the more terrified that Johnny was to be "butchered like a pig."

However, Johnny responded to the adrenalin injection and no tracheotomy was performed, but the doctor did explain the reason for considering a tracheotomy. However, to him, it still sounded like a plan to butcher Johnny.

After the doctor left, his father trounced him so hours by Johnny's bedside and to watch and give the alarm if Johnny developed "breathing trouble so he would have to have his throat cut."

All that night he dreamed of Johnny's skin turning a "horrible green like the horse trough." The next day he was forced to watch the doctor redress the wound, the surrounding area of which was "all awful color, green and nasty." Furthermore, the doctoring in examining the wound remarked that it was a most “nasty thing.” Later that day he neglected to pump water for the horses, and was again thoroughly spanked by his father while in the same position as the previous day.

Shortly thereafter Johnny's parents moved out of state, and all contact was lost. As far as he could determine, the entire matter then became a closed incident, and a year later his parents moved to a distant city, and farm life became a forgotten thing.

Tired, exhausted, self-absorbed, the student took his departure with the others, who had been instructed not to discuss the matter till later.

A week later the student visited the writer, stating that he had learned some amazing things about himself as a result of his recovered memory.

First of all, he doubted if he was as seriously interested in psychiatry as he had previously thought. Internal medicine was proving more interesting.

Secondly, his attitude toward dermatology had changed completely. Previously, he had been unable to study the textbook, despite repeated efforts. Either he went to sleep or immediately became distracted. Each time he went to the dermatology clinic, he became sick and had to leave. Also, despite frequent faculty warnings, he had consistently avoided the lectures given on the subject. Now he was studying dermatology with interest, and he enjoyed the clinics. (He eventually secured a good grade in that subject.)

He was seen regularly in class sessions for the rest of the year and also throughout his internship, during which time he discussed his future plans, which included a residency in internal medicine. However, he still retained a good, though secondary, interest in psychiatry.

He has since completed a residency in internal medicine and is now in private practice, utilizing his knowledge of psychiatry extensively in handling his patients.

CONCLUSION

Little need be said in summary about the in formativeness of the student's performance. The directness, the economy of effort and time, the effectiveness with which he accomplished his

task, and the significance of the results to him as a personality, together with the ease with which one can follow and understand what occurred, is most impressive. It is difficult even to imagine such a task performance in the ordinary waking state, even as the student himself discovered. Yet, in the hypnotic state a seemingly impossible task became comprehensible, feasible, and ready of accomplishment in a recognizable fashion.

Self-Exploration in Trance Following a Surprise Handshake Induction

Milton H. Erickson

Unpublished manuscript, 1952-1954. A detailed analysis of the dynamics of the handshake induction is provided in Erickson, Rossi, & Rossi, 1976.

A medical man who had used hypnosis for many years suffered the tragic loss of his oldest son, who had been his first hypnotic subject. The man reacted to this by a severe depression, following which he abandoned hypnosis and practiced his profession at a minimal level. After approximately seven years he attempted to resume the use of hypnosis, but each time he found himself seriously blocked psychologically, stumbling for words, becoming confused, and reacting with a brief severe depression at each failure.

He sought therapy in a rather rigid, compulsive way, entering the office, placing a check on the desk, and explaining, "That will pay you for your time. All I want is to have you hypnotize me, remove my block against hypnosis, and send me on my way." Reluctantly, he gave the above information and insisted upon the therapist proceeding forthright with no other preliminaries. He sat rigidly upright in his chair, arms folded across his chest, and stared unblinkingly at the therapist, following every movement made. The suggestion that he lean back and relax elicited the answer, "I'm perfectly relaxed—just go ahead and try to hypnotize me. I've given you a check large enough to pay you for the next two hours of your time."

INITIAL FAILURE AT TRANCE INDUCTION TO DEPOTENTIATE RESISTANCE

Against this background of resolute, insightless resistance the therapist made a seemingly intense effort at hypnotic induction, employing first one and then another induction technique, taking care each time to force issues unduly or to fail to take advantage of any slight yielding to suggestion. Thus, failure of the effect to induce hypnosis was ensured. Now and then, as the therapist continued his efforts, the patient was observed to smile. At the end of two hours' intense effort absolute inability to induce a trance was admitted. The patient smiled graciously, reassured the therapist that it did not matter, that he was merely on his way to the Grand Canyon and had stopped in only as an incidental visit to see if he could be hypnotized. Now that he knew this could not be, he would abandon his search for therapy.

A SURPRISE HANDSHAKE INDUCTION

After shaking hands with the patient and bidding him a pleasant trip, it was suggested that he might like to meet the therapist's wife (the office is in the home). He consented, the

introduction was made in another room, casual remarks were made about his trip, and he was again bidden farewell. The therapist again shook hands with the patient in a normal, vigorous fashion. However, the hand was withdrawn in a slow, lingering, indefinite fashion that served to fixate the patient's attention completely, to induce a state of catalepsy and a profound somnambulistic trance. He was immediately led into the office, assured that his purpose in seeking hypnosis had been achieved, and that he should spend the next hour primarily in thinking through and understanding his total life situation, using the therapist merely as a sounding board for ideas.

The patient sat quietly, now and then murmuring inaudibly to himself, now and then asking some simple question pertaining to the therapist's opinion about his future use of hypnosis and his reestablishment of his full practice. Simple reassurances were given.

At the end of the hour the patient was aroused from his trance state, congratulated on his competence as a subject, and asked to keep in touch with the therapist by mail should problems arise in his use of hypnosis in his practice. Then he was again bidden farewell.

Eight years have elapsed. The patient has a full and active practice, is enthusiastic in his use of hypnosis, and has encountered no further difficulties.

Reorganization of Unconscious Thinking without Conscious Awareness: Two Cases with Intellectualized Resistance against Hypnosis

Milton H. Erickson

Unpublished manuscript, 1956.

CASE 1: THE REORGANIZATION OF UNCONSCIOUS THINKING WITHOUT AWARENESS

A 40-year old patient, suffering from a chronic respiratory disease of a progressively disabling character, sought hypnotherapy for long-continued excessive smoking, amounting to three to four packs of cigarettes daily. The explanation was offered by the patient that the smoking was entirely compulsive, that there was no possibility for self-control, and that hypnotherapy had been sought repeatedly without avail. Now, as a final endeavor, hypnotherapy was once more being sought as "a final despairing gesture." This phrase was explained as signifying the patient's absolute conviction that any attempt at hypnosis would fail.

TRANCE INDUCTION WITH AN ASSOCIATIVE NETWORK OF TRUISMS

The therapist silently agreed with the patient, who sat watching every move made with almost pathological intensity. However, the patient demanded that an effort at hypnosis be made and seemed both relieved and disappointed when he did not experience any recognizable hypnotic response after half an hour of systematic trance induction. The patient demanded further effort, but was dissuaded by the therapist, who suggested the following:

1. The patient was to fixate visually upon the corner of a desk clock—"to hold the eyes still."
2. The soft ticking of the clock was to be attended assiduously—"to hold the ears still."
3. Random thoughts, orderly thoughts, systematized thoughts were to be free to wander through the mind freely and spontaneously or even to linger.
4. At all times the patient was to feel wide-awake, alert, and attentive to the adequate performance of the tasks assigned or to be assigned. At any hint of any hypnotic suggestion or attempt to induce a trance, the patient was to give full attention to the therapist and to disrupt thereby the assigned tasks.
5. Although paying attention to the ticking of the clock, there could be any degree of additional auditory awareness of sounds within the office, in the next room, outside the office, in the street, in the skies.

6. There was also to be a constant awareness of the physical self, with attention fluctuating from one part of the body to another, from the feet to the hands or the thighs, to the cloth around the neck, to the hair on the head, and back again with any variation desired.
7. At all times the patient was to feel free to listen consciously to whatever the therapist said, but this, it was explained, was actually unnecessary, since the constantly present unconscious mind would be within hearing distance of the therapist and could listen by itself while the conscious mind busied itself with the clock, with thoughts, with various sounds, and whatever else interested it, including the fluctuations in body awareness.
8. At the close of the interview the eyes and ears would slowly shift their attention from the clock to the therapist.

The patient was most cooperative, obeying instructions excellently. Within five minutes he presented the appearance of a deep trance state. This was tested, after 10 minutes, by laboriously searching the desktop for a manuscript, during the process of which the clock was apparently "thoughtlessly" removed from its position and obscured from the patient's view. This resulted in no visible response on the part of the patient, whose gaze remained fixed and unchanged at the spot where the clock had been. The pupils were noted to be widely dilated, as is frequently the finding in deep hypnosis. Neither was there any apparent awareness of the therapist leaving his seat and wandering aimlessly about the office. Nor did the patient seem aware of a sudden noisy flight of jet planes overhead.

Therapy was accomplished by discussing matter-of-factly the patient's physical needs to discontinue smoking and by raising the question variously of the relative values of smoking, physical health, freedom from compulsion, and peace of mind.

As this discussion was offered, the patient was admonished from time to time to continue fixating on the clock, both auditorily and visually, to entertain any variety of conscious thoughts of interest, to hear and to be aware of whatever was desired, but above all to know that conscious activity was relatively unimportant in the therapeutic situation, that *the only thing of paramount importance was the reorganization of unconscious thinking taking place without conscious awareness*.

The patient was seen for a total of 11 hours over six days in one month. About half that time was spent in futile attempts to "hypnotize me," at the patient's urgent request, and in social chitchat far afield from the problem in hand. The rest of the time was spent in actual therapy essentially as described above. The therapeutic result was the reduction to three postprandial cigarettes and one just before going to bed.

The next month the patient returned with the plea that the remaining cigarette smoking be abolished, since it constituted the "doorstep for the reentry of the old habit." At this time a hesitant request was made several times for the use of hypnosis, but on each occasion the patient was fully as resistant as originally. Each time an apology would be offered,

and the suggestion would be made by the patient that resort be had to the clock fixation "because that way I listen better."

The same routine as before was instituted with one exception: the smoking, which had been excessive since puberty, was a secondary matter. Present-day problems pertaining to finances and family matters were brought up for discussion. A total of 16 hours over a period of eight days was spent, about one-fourth in directed chitchat to elicit information and attitudes and the rest of the time as described above, but this time discussing the immediate problems other than smoking, which in five days was discontinued.

Upon the closing of the case, the patient expressed regret at the failure to develop a trance state and wonderment at a marked inability to perceive the passage of time correctly during therapeutic sessions. No request of any sort was made for any explanation of this, although in discussing matters with the patient's "unconscious mind," suggestions were offered that the patient should feel free to request explanation of any item not fully understood.

CASE 2: TRANCE INDUCTION WITH A SURROGATE THERAPIST

Comparable to the foregoing case was that of another patient, also a physician, who telephoned long-distance demanding a specific appointment for hypnotherapy at a specific hour, suggesting that any conflicting appointments already made be canceled. After some discussion an appointment was finally scheduled, but the day before he again telephoned long-distance to inquire if the therapist were prepared to abide by the wishes and needs explained over the telephone. A placating answer was offered, and preparations were made for his arrival.

He appeared promptly on time, walked briskly into the office, introduced himself, stated that he was a physician, well aware of his own needs, and demanded that he "be hypnotized if you think you can do it" without further history-taking or delay. He sat himself comfortably in the chair, leaned back, cocked his head to one side, smiled in a superior fashion as he folded his arms, and said, "Go ahead."

With equal insistence the therapist demanded a minimum of vital information about him, and the patient reluctantly agreed that he himself would so demand of a patient. When this was completed, the patient commanded, "Now go ahead, and use a dominating technique because I am a dominant personality. Take about 15 minutes. That will tell the story."

For about 15 minutes a strongly authoritarian technique was carefully employed, while the patient smiled condescendingly. After glancing at the clock, the patient ordered, "You might as well keep on for another 15 minutes, even though you are not going to get anywhere."

As predicted, the patient made no response to this approach, nor was one expected. The patient made a few caustic comments and then asked if the therapist knew any method by which hypnosis could be induced.

Answering affirmatively, the therapist immediately stepped out of the office and returned almost immediately with a young woman. Without further ado she was instructed to develop a somnambulistic trance, which she did promptly. She manifested spontaneously a negative hallucination for the patient, and this was corrected by having her become aware of his presence. She was then instructed to sit quietly in the therapist's chair and, using a soft gentle technique, induce a profound somnambulistic trance in the patient while the therapist absented himself from the office. Upon his return in about 15 minutes she was to transfer rapport to the therapist and then to leave the office, arousing from the trance immediately after her exit.

The therapist returned in about 15 minutes. The patient and the young woman were both in somnambulistic trances. The young woman fulfilled her instructions and departed.

The question of therapy was then taken up with the patient, and in the trance state he was found to be receptive and cooperative; it was possible to arrange with him to let the therapist govern the course of the therapy. Despite the patient's disturbed condition extensive and effective therapy was accomplished, sometimes with and sometimes without the use of hypnosis, as the immediate situation indicated.

Psychological Shocks and Creative Moments in Psychotherapy

Ernest L. Rossi

This paper was written by Ernest L. Rossi who expresses his appreciation to Milton H. Erickson for providing the case material and inspiring the discussion of its theoretical issues. He and his wife, Elizabeth Erickson, have generously contributed time, effort and editorial experience in its preparation.

Reprinted with permission from *The American Journal of Clinical Hypnosis,* July, 1973, 16, 9-22.

During the summer of 1972 Milton H. Erickson was quietly reminiscing over his 50 years of creative experience with hypnosis while Rossi gently probed with a question or two as he maintained the adjustments on his cassette recorder. It soon became evident to our mutual surprise and delight that Erickson was now giving expression to a basic aspect of his work that he had never really emphasized before-psychological shock. Shock could be creatively utilized in psythotherapy (with or without hypnosis) to break up maladaptive attitudes and patterns of behavior so the therapist could help the patient realign his life learnings in a more constructive manner. As Erickson illustrated his views with many case histories from his clinical practice, Rossi gradually began to recognize the necessary relation between psychological shock and the development of creative moments that he recently described as the basic dynamic of change in psychotherapy (Rossi, 1972a). In this paper we will first present a number of cases where Erickson successfully utilized psychological shock; we will then make an effort to describe the psychotherapeutic circumstances necessary for the safe and successful use of psychological shock; we will then outline some of the theoretical issues dealing with psychological shock and creative moments in their relation to hypnotherapy.

CASE 1

A 30-year-old university professor attended a university dance and saw a 30-year-old single woman on the other side of the room. She saw him, and they rapidly gravitated toward each other. Within a month they had planned their future and were married. Three years later they appeared in Erickson's office and told their sad story. In telling it they were extremely prudish and embarrassed, and they used a most stilted and formal wording. In essence their complaint was that even before marriage they had planned to have a family, and because of the fact that they were each 30 years old, they felt that there should be no delay of any sort. But after three years they were childless despite medical examinations and advice. They were both present in the office, and in telling the author their problems, the man said:

> In my thinking and that of my wife we have reached the conclusion that it is more proper that I give voice to our trouble in common and state it succinctly. Our problem is most distressing and destructive of our marriage. Because of our desire for children we have engaged in the marital union with full physiological concomitants each night and morning for procreative purposes. On Sundays and holidays we have engaged in the marital union with full physiological concomitants for procreative purposes as much as four times a day. We have not permitted physical disability to interfere. As a result of the frustration of our philoprogenitive desires, the marital union has become progressively unpleasant for us, but it has not interfered with our efforts at procreation; but it does distress both of us to discover our increasing impatience with each other. For this reason we are seeking your aid, since other medical aid has failed.

At this point Erickson interrupted and said to the man, "You have stated the problem. I would like to have you remain silent and have your wife state the opinion in her own words." In almost exactly the same way and with even greater embarrassment than her husband had shown, the wife voiced their complaint. Erickson said, "I can correct this for you but it will involve shock therapy. It will not be electric shock or physical shock, but it will be a matter of psychological shock. I will leave you alone in the office for 15 minutes so that the two of you can exchange views and opinions about your willingness to receive a rather severe psychological shock. At the end of 15 minutes I will come back into the office and ask your decision and abide by it."

Erickson left the office and returned 15 minutes later and said, "Give me your answer." The man said, "We have discussed the matter both objectively and subjectively, and we have reached the conclusion that we will endure anything that might possibly offer satisfaction for our philoprogenitive desires."

Erickson asked the wife, "Do you agree fully?" She answered, "I do, sir."

The author explained that the shock would be psychological, involve their emotions, and be a definite strain upon them.

> It will be rather simple to administer, but you will both be exceedingly shocked psychologically. I suggest that as you sit there in your chairs, you reach down under the sides of your chairs and hang tightly to the bottom of the chair and listen well to what I say. After I have said it, and as I am administering the shock, I want the two of you to maintain an absolute silence. Within a few minutes you will be able to leave the office and return to your home 40 miles from here. I want the two of you to maintain an absolute silence all the way home, and during that silence you will discover a multitude of thoughts rushing through your minds. Upon reaching home you will maintain silence until after you have entered the house and closed the door. You will then be free! Now hang tightly to the bottom of your chairs because I am now going to give you the psychological shock. It is this: For three long years you have engaged in the marital union with full physiological concomitants for procreative purposes at least twice a day and

> sometimes as much as four times in 24 hours, and you have met with defeat of your philoprogenitive drive. *Now why in hell don't you f— for fun and pray to the devil that she isn't knocked up for at least three months. Now please leave*.

As was learned later, they maintained silence all the way home thinking, "many things." When they finally got inside the house with the door shut, it was explained, "We found we couldn't wait to get to the bedroom. We just dropped to the floor and we didn't engage in the marital union. We had fun, and now the three months are barely up and my wife is pregnant." Nine months later a baby girl was born. When Erickson called on them to see the baby, he learned that formal speech and polysyllabic words and highly proper phrases were no longer necessary in their conversations. They could even tell risque stories.

This case history was related in full to an audience of over 70 practicing psychiatrists at Columbia University at the request of Doctor Herbert Spiegel. Preliminary to narration of the case history, Doctor Spiegel and Erickson had been discussing the ingrained attitudes of inhibitions for what are so-called Anglo-Saxon words, and the audience was asked if they thought that they could endure listening to the author make use of such words in relation to a psychiatric problem. The audience and Doctor Spiegel were certain they could, and Erickson also felt that they could. However, to the utter astonishment of Erickson, at the utterance of the key word he noted that the entire audience actually froze into rigid immobility for a few moments. Doctor Spiegel was noted to catch his breath, and Erickson noted that his own tone of voice very definitely changed. This was most revealing about the long-continued effects of the learned inhibitions of childhood and their continuance into adult life.

In Erickson's opinion the 40-mile drive in absolute silence made possible, in accord with the suggestions given them, a great variety of much repressed thinking that ran riot in their minds. This resulted in their sexual activity immediately upon closing the door when they reached home. This was what Erickson had hoped. When the couple were questioned about this, they stated that they believed that there had been an increasingly greater build-up of erotic thinking the nearer they got to their home, but they stated that they had no specific memories.

CASE 2

Erickson: A soldier in Yuma courted a Spanish-American girl whose mother was widowed while the girl was still very young. She had been escorted to grade school and high school by two maiden aunts and then escorted home again every day. They went to every child's party, every school party, every high school outing, football game, what have you. They went with her when she applied for a job as secretary. They took her to work, called for her at noon, took her out to lunch, escorted her home in the evening. At some football game this soldier stationed in Yuma was attracted to the girl. The two old maids went on every date. Somehow or other he proposed to her, properly and in the presence of the old maids. She promised to marry him, and he was allowed to kiss her once. She promised to marry him in June. In June she promised to marry him in

July. In July she promised to marry him in August. That went on for 48 months—continuous delays.

Then the family physician called me up and said "I can't do anything with this girl." The girl had been escorted to the family physician's office and was properly chaperoned when the physician examined her. He called me when they left, "Would you take her?" I said, "Yes." So her mother and the two maiden aunts came with her on the bus to my office. They were horrified when I wouldn't let them come into the office with her. The mother and two aunts were forced to sit outside the door so I could see the girl alone. The girl told me the situation. I asked her if she wanted to marry the boy. She did. That was in June. The first of July she got a letter from him saying, "We're going to be married this month or I'm going to get another girl." She was most tearful. So I asked her, "Are you sure you want to marry that boy? Are you really, really sure?" She was. I told her "I can help you, there's only one thing you have to do—come from your home to my office alone. I know you're afraid to ride on the bus alone, you're afraid to ride in a car without your aunts, you're afraid to ride on the train without your aunts, but you come from Yuma, alone.

"Now, I don't care where you do it. You can do it in Yuma or in Phoenix: you buy a pair of short, short pants and come into my office wearing them, and when you come into the office, you are going to do exactly what I tell you to do. Absolutely, exactly, without protest without question. You'll silently do what I tell you to do. You'll think it over for a long, long time, and do you know, you're going to do it, you'll say 'I will, I absolutely will.'"

On her next appointment I had Mrs. Erickson in the office. Mrs. Erickson didn't know what I was going to do. The girl came in and sat down in a chair, I introduced her to Mrs. Erickson. I told the girl to just stand there, facing me, hands to her sides. "Now look straight ahead ... take off your left shoe ... your right one ... take off your left stocking.... your right stocking . . . take off your shorts . . . take off your blouse ... take off your bra ... take off your panties ... point to your right nipple ... your right breast ... your left nipple ... your left breast ... your belly button ... your pubic genital area ... turn around, point to your right buttock ... your left buttock ... turn around, face me, tell me if you have a beautiful body.... All right, you do have a beautiful body. You may dress. Before you marry that man you'll board the train and go back to Yuma alone. You will tell your mother that you are getting married, and you will tell your mother what kind of wedding cake you want. You will tell your mother who the guests will be and you will tell your mother that if she thinks otherwise, you are going to be married by a justice of the peace (a terrible threat since they were Catholics)."

That was the beginning of July. She married on July 17th. She sent me a Christmas card in December with a picture of herself and her husband. The next year, she sent me a picture of her first child and Christmas cards on the following years announcing her second and third child. A few years later she brought the family with three children in to see me.

Rossi: Okay, how did that case work? Was shock involved?

Erickson: Could there be anything worse than undressing before your doctor in the presence of his wife and pointing to your nipples and your breasts and your belly button?

Rossi: She was never in a trance?

Erickson: No.

Rossi: Except what the situation might have induced.

Erickson: That's right, except for what the situation induced.
Rossi: There might have been an altered state of awareness that arose spontaneously due to the shock situation she was in. So what you did was to break through tremendous inhibitions.

Erickson: Great inhibitions—nothing worse ever happened to her.

Rossi: Having forced those responses, you broke through the lifelong pattern of conditioned inhibition of having those aunts around and so forth.

Erickson: Yes, it disrupted the rigidity that governed her entire life. Just as the first break in the shell pecked by a newly emerging chick immediately shatters the whole shell, so her whole life opened up. I just gave her simple statements. You do this, do that, no questions, just do it silently.

Rossi: And those simple statements, that you point to your breasts, your genitalia and so forth, what were those statements designed to do?

Erickson: To break her inhibitions, really break them! Notice how I engineered that: first the left shoe, then the right, the left stocking, and then the right. I carefully built up a momentum of an affirmative character so she finally took off all her clothes and followed all my suggestions designed to shatter her lifelong inhibitions. I made her promise to do everything. Anyone like that who gives a promise....

Rossi: Ah, that's how you had her caught in a double-bind, so to speak. I notice that before you do this shock type therapy, you demand a promise of obedience, do you not? And the patient has to have a mental structure, I suppose, where they are going to go along with you. They are the kind of people who will keep a promise, and you capitalize on that. A psychopath you could not do this with.

Erickson: I can't imagine doing it with a psychopath, I wouldn't even try.

Rossi: It would have to be some who had a lot of ...

Erickson: ... Innate honesty.

Rossi: It occurs to me, was this therapy a symbolic rape?

Erickson: It was a rape.

Rossi: Did you think of it that way when you were planning it, as a symbolic rape?

Erickson: I did, it was a psychological rape.

CASE 3

Erickson: A professional man and his wife consulted me. He began by saying that they have been married 12 years. "We have a daughter, but apparently we are not going to have another child. This is the way we go to bed. I have to go to the bedroom, shut the door, undress, put on my pajamas. Get into bed then call my wife. She comes, turns out the bedroom light, all of the lights. Then first she draws the shades, and then the drapes over every window. She checks the doors, to make certain they're locked, the windows are locked. She turns out all the lights. She goes into the guest room and she undresses there, in the dark. She puts on her nightgown. Then she comes through the darkened hall into the dark bedroom and she gets into bed with me. I can have sex relations with her, I can even take her nightgown off, but the lights cannot be turned on. She will not allow me to see her nude."

I then said to her, "You've had one child, the lights were on and your nude body was seen by your obstetrician and nurses, and you're still alive. Now your husband wants this corrected."

She said, "But I can't do what he asks, I just can't let him see my body."

I said, "Well, that's your statement, `I can't do it.' Now your husband is six foot two, weighs 210 pounds, able-bodied. I have a bad limp. I'm five foot six, weight 150 pounds. There's no question that I'm outmatched physically by your husband. I want you to sit quietly in that chair. Your husband's going to make you sit there. I can tell you and I mean it, you sit there. Now I'm going to do something to you, and I want your husband to watch." At that time the style of the skirts was down to mid-calf length. "Now I'm going to start moving your skirt a little bit over your thighs, I'll stop moving them only when you are in a deep trance. And you'll listen to me. And you'll not say you can't." Half an inch at a time I slowly began lifting her skirt. This was an unendurable thing for her to be aware of consciously, therefore her only escape was to go into a trance. She was aware of my use of hypnosis, since I had treated a friend of hers.

Rossi: Now this was setting up a double-bind, going into a trance that way.

Erickson: Yes. I slowly lifted her skirt, up and up past the knee. She was just looking at her skirt and my face.

Rossi: Yes, she went into a trance.

Erickson: "Now you're in a deep trance. I don't know why you've been having this foolish undesirable behavior for 12 long years, more than 12 long years, actually 13 years, before your daughter was born. But I want you to understand that you're going to change things. You'll not do it all at once. I'm not going to ask you to do it in my presence or your husband's presence. Each day at home, after your daughter's gone to school, and you're alone in the house, I want you to look in every mirror in the house. [A house is a woman's castle, her own protected territory in which she could feel free to experiment.] And look at that woman and wonder what she looks like, and I want you to discover bit by bit what she looks like in the nude, completely in the nude. Take off her clothes bit by bit. First the shoes, then the stockings, then the dress and the slip. The bra, the pants. Then I want you to dance. You will dance as a child, a ballet dance. You did ballet dancing in college. You'll enjoy dancing. You must within six months, perhaps after three months, undress in the guest room, in the dark, then walk into the bedroom, turn on the lights, and do a ballet dance for your husband in the nude.

Rossi: This was all said while she was in that trance state and her husband was present?

Erickson: Her husband was present. She could effect the cure at the right time at her own speed.

Rossi: Yes, very important that you allowed her unconscious to do it at its own rate.

Erickson: Its own rate, its own fashion. First the shoes, then the stockings. Or she'd take off her slip first or she'd take off her bra and her dress first, it didn't make a bit of difference to me.

Rossi: Right, this is all the freedom that you gave her.

Erickson: I placed the limit of within six months, and I offered her a period of three months to experiment by herself. This establishes the illusion of freedom of choice.

Rossi: Setting these definite time parameters within which she could have all the freedom she needed.

Erickson: You can imagine her husband's delight when she pranced in her bedroom, switched on the light, did the ballet dance for him in the
nude.

Rossi: He must have been happy. So with that happening, presumably she was over her inhibition.

Erickson: Yes, and how! Now there's one thing I had said to her, "If you don't do it, your husband will bring you back here and you will do a nude dance for me in your husband's presence."

Rossi: It was going to be worse if she didn't do it for her husband since she'd have to do it for you too. So again you set up a double-bind. It was going to be harder if she didn't do it alone for her husband, so you gave her the easy way out.

Erickson: A very easy way out.

Rossi: You use a carrot but you use a whip too, don't you?

Erickson: There's iron under my velvet gloves.

Rossi: I'm becoming more and more impressed with that.

Erickson: Now, why should I investigate her past? The parental influence on her, her father's, her mother's, her teachers'. Why should I do anything at all by way of going deeply into her personal history? Therapy is often a matter of tipping the first domino. All that was needed was the correction of one behavior, and if that one behavior was corrected ...

Rossi: All the other inhibitions topple like dominoes.

Erickson: Yes, we have a domino situation.

Rossi: Yes, perhaps the early analyst had to go back into a patient's history to learn psychoanalysis, to learn how those inhibitions were built up. But since we know all that, you don't have to go into it with each patient.

Erickson: It's so ridiculous to pore over what you did when you were five years old because it belongs to the unchangeable past and any present understandings of that are different than that of the five-year-old. The adult level of understanding precludes any real understanding of the child's or adolescent's world.

CASE 4

Erickson: Another shock case. This is such a beautiful one. Mary and Eve had been grade school and high school friends. They both married high school friends, and the two men were also high school friends. They both told me they confided everything to each other, and they both confided that they had to get a divorce. Each said her husband was a pervert, but neither admitted, neither dared to tell the other just what the perversion was. So in separate interviews I asked each girl to describe her husband's perversion to me. Mary said when a man and a woman have intercourse, a man's legs are between the woman's legs. And her husband always wanted to keep his legs outside her legs. Now when I later interviewed Eve, she said the exact reverse. She felt it was normal for the man to have his legs outside the woman's, but her husband perversely wanted to keep his legs between hers. I saw both girls at four o'clock on successive days. I told them not to tell each other what I had said or what they told me. And then the third day I had them

come together for a joint interview. By this time they both had time to build up a lot of inner turmoil and emotion. I told them, “When one of you speaks to me, the other just listens and says nothing (this silence was to build up even more emotion).” Then as one told her story, the other would just listen to her. First Eve told about her husband insisting on keeping his legs between her legs. And then Mary told the reverse story. Their mutual horror is imaginable. Then I summarized how they both told their story and listened to each other most attentively in silence. Now they were to drive home together maintaining their silence all the way. “Now when you get home you will both have the urge to ask the other, what the hell is wrong with you?”

Rossi: I see, they had to be silent on the way home, so it would build up within their minds....

Erickson: It would build up: what in the hell is wrong with you! They both had to say that to the other. Then they could talk. Think of the horrible buildup!

Rossi: Again, building up that tension to be discharged in a new way.

Erickson: Each had intercourse that night both ways and both enjoyed it.

Rossi: Fantastic. So here’s another shock therapy involving a sexual problem, a sexual inhibition.

Erickson: It was more than a sexual inhibition. It was based on an insufficient awareness of human behavior.

Rossi: I see. That was their inhibition-a lack of awareness of the broad range of human behavior.

Erickson: Yes, and a rigid idea.

Rossi: Yes, so that’s what shock therapy does. It breaks through rigid ideas.

Erickson: Rigid ideas they couldn’t break. And when I shattered that rigid idea, it shattered the hell out of them. It even led them to try other positions. I hadn’t told them there were other positions, they started investigating other positions on their own.

Rossi: Once you broke their rigid idea of only one set position....

Erickson: It altered the place they could go for pleasure. It was a breakdown of a narrow, limited, restricted life existence. You can’t be rigid in one area alone; it always spreads.

Rossi: So again, it’s not mere behavior you’re changing, but a whole existence.

Erickson: And you pick whatever lock is presented to you.

Rossi: I see, so this is as much existential therapy as behavior therapy or hypnotherapy. It's the total existence that you....

Erickson: It's an old thesis.

Rossi: You pick whatever lock is presented to you.

Erickson: And once one lock is picked, all the other locks become vulnerable. [Erickson now elaborates many examples in the history of science where great advances were made by one man breaking through the inhibiting preconceptions of others.] Throughout history there has been a lot of shock therapy.

Rossi: Perhaps the whole history of innovation is shock therapy. Every scientific innovation is a shock therapy.

CASE 5

Erickson: American Jews aren't always orthodox—in fact, many Jews aren't. But this is the case of a very orthodox Jewish girl who came from a European family that observed all the most elaborate rules about food. They left Germany because they realized that Hitler boded no good for the Jews. Her father had to sell out all his belongings at a great loss. So great a loss that it shattered their former life-style, and this shattering permitted them to change. They took on the break that Hitler forced upon them and made it their own by breaking former traditions. They thus gave up bitterness and gave themselves a chance for happiness in America. This allowed them to encourage their daughter to change. Her parents were older and knew they could not change, but they encouraged the girl to adopt more liberal views so she could marry an American doctor who had proposed to her. He had insisted on a more liberal home. She said, "I want to marry him but I'm kosher." I said to her, "You are no longer German Jews, you're going to be an American citizen, you've already applied for your first papers. You're in love with an American Jew. He's a doctor who knows his business. He's got my respect. But he likes bacon and ham and he doesn't believe in two sets of kitchen utensils. I want you to eat a ham sandwich right now."

Rossi: You said this directly to her just like that!

Erickson: I told her to go across the street and get a ham sandwich, have the man wrap it and bring it to my office. You'll slowly unwrap it, first bite, the second, the third.... You won't believe you can possibly eat it, but I've never seen a person die so I'll be glad to watch you eat it and die while you are eating it. Now there is nothing colder and harder than watching a person die. The fact that she doesn't die even though I said I would watch her die forces her to face the complete absurdity of the idea. The inhibition was shattered by a reductio ad absurdum. Can you imagine how she ate that sandwich?

Rossi: You tell me—a lot of inhibition, I suppose, or could it possibly have been with relish?

Erickson: With tension and fear. I watched her closely with a straight face. When she was half through with the sandwich, I said, "Wouldn't it be pure hell if you found the sandwich tasty?" She is now happily married.

Rossi: Again the shock was used to shatter lifelong inhibitions by forcing her, right there in your presence ...

Erickson: No. I'm not forcing her. I'm watching her die, but she is eating the sandwich. The burden is on her for eating the sandwich.

Rossi: Oh, I see. The burden for the critical behavior change is always on the patient. You know, this begins to sound a little like some of the behavioristic techniques of helping a person to overcome a phobia by accompanying them on a certain journey ... to a height, for example. Do you see a relation?

Erickson: Well, Wolpe says its behavioristic. But I think its more experiential.

Rossi: I see, it's their experience that's the important thing.

Erickson: Yes, and I'm definitely on the outside.

Rossi: How do you mean, you're on the outside?

Erickson: I'm just watching her eat, and she is eating so I can watch her die.

Rossi: Yes, and it's not the mere behavior of eating, but the whole experience, all of her inhibitions, all her lifetime associations, these are the things that are being broken. It's not the mere behavioristic act of putting ham in her mouth.

Erickson: Yes, you have expressed that quite well; it's the total experience.

CONDITIONS FOR THE SAFE UTILIZATION OF PSYCHOLOGICAL SHOCK

So unusual and obviously risk-laden are these examples of psychological shock therapy that the average, responsible therapist may feel inclined to throw up his hands and silently decide to leave this approach to a few master therapists who somehow know how to handle it. A careful review of Erickson's work, however, does reveal a number of conditions that appear again and again in many different guises when he illustrates the successful use of psychological shock. They may be summarized as follows:

1. Psychologically Binding Conditions

The most important condition for the safe and effective use of shock is that patient and therapist are bound together in therapeutic encounter by powerful psychological forces.

C. G. Jung (1953) has used the ancient concept of the *temenos* (sacred precinct) to describe the psychologically binding conditions that are necessary to contain a conflict in order to permit a safe personality transformation to take place without the person being shattered by internal chaos or extraneous external circumstances. On a cultural-anthropological level, for example, the psychological shock and pain that is a regular feature of many initiation rites designed to promote personality change is safely contained in the *temenos* of the belief-system adhered to by initiators and initiates. In modern psycho-therapy it is the *transference* or the *prestige* of the therapist that binds patients to the conflict-laden task of change. In its simplest form Erickson actually sets up morally binding conditions where he demands obedience when he knows he can get it. This is most clearly illustrated in Case 2, when he demands of the virginal girl, "Absolutely, exactly, without protest, without question, you'll silently do what I tell you to do." In cases 1, 3, and 4 the *temenos* contained husband and wife or friends who were required to interact in such a manner that their rigidly maladaptive patterns were shattered so something new could happen.

2. Protecting the Patient

Implied in the above is that the patient must be protected at all times. In Case 2 Mrs. Erickson was present as a chaperone during a critically important nude encounter; in cases 1 and 3 a spouse was present. Far more subtle is the protection that must be provided for the deeper levels of personality. Although Erickson admits, "There's iron under my velvet gloves," he makes an obvious effort to be scrupulously circumspect in respecting the patient's dignity. Erickson has previously described this need to protect the subject in his discussion of deep hypnosis and its induction (1967a).

3. A Central, Strategic Issue Is Dealt With

In his discussion of the domino situation in Case 3, Erickson makes it clear that psychological shock is to be used to jolt the basic crux of the patient's problem. Once a crucial behavior is actualized (eating a ham sandwich in Case 5), a rigid belief shattered (the "perversions" of the girls in Case 4), it is *suddenly* possible for many behaviors, attitudes, and inner experiences to change. Erickson reiterates this view with his lock analogy in Case 4—"And once one lock is picked, all the other locks become vulnerable."

4. Tension Is Kept High

Tension is not a mere epiphenomenon in psychological shock therapy. Erickson frequently sets up circumstances where tension will build in the therapeutic situation so that energy can suddenly be discharged in more desired channels. The clearest example of this is in Case 1 where Erickson (a) gives a psychologically weighty' forewarning to the couple that he is going to use "shock," (b) allows the tension of that forewarning to build as he deliberately leaves the therapy room so the couple can privately discuss whether they want to take the "risk" involved, (c) tells them to hold on to the seat of their chairs as he is about to deliver his shock, and (d) most importantly he demands that they

remain silent all the way home after he delivers his shock, so it will not be dissipated by needless intellectual discussion. In particular this maneuver of demanding silence during certain crucial periods is a way of building and maintaining optimal therapeutic tension (as well as *fixing the patient's attention*) very frequently used by Erickson.

5. Changing Behavior by Setting Definite Time Limits

Therapy is obviously doing as well as understanding. A certain amount of therapeutic acumen is needed to determine whether a patient is ready for immediate behavior change (as in Case 5, where the Jewish girl's orthodox parents had already encouraged her toward more liberal attitudes, so Erickson recognized she was probably ripe for the immediate behavior change of eating a ham sandwich) or a more leisurely pace of inner growth and transformation. In Case 3, where Erickson recognized it was going to take more time to radically change a lifelong attitude of prudishness, he (a) carefully set time parameters (between three and six months) within which the desired change was to take place, (b) carefully protected the patient by allowing her to experiment with nudity by herself at first, and (c) helped her to make the desired change by associating the difficult problem of nudity with her skill and joy in dancing. The setting of definite time parameters for psychotherapeutic change may be something more than borrowing a leaf from Otto Rank's time-limited approach to therapy: Time is required for the actual process of psychotherapeutic transformation, to which we will now turn our attention.

PSYCHOLOGICAL SHOCK AND CREATIVE MOMENTS IN HYPNOTHERAPY

Rossi (1972a) recently described *creative moments* in therapy as follows:

> But what is a creative moment? Such moments have been celebrated as the exciting "hunch" by scientific workers and "inspiration" by people in the arts (Barron, 1969). *A creative moment occurs when a habitual pattern of association is interrupted*; there may be a "spontaneous" lapse or relaxation of one's habitual associative process; there may be a psychic shock, an overwhelming sensory or emotional experience; a psychedelic drug, a toxic condition or sensory deprivation; yoga, Zen, spiritual and meditative exercises may likewise interrupt our habitual associations and introduce a momentary void in awareness. In that fraction of a second when the habitual contents of awareness are knocked out there is a chance for pure awareness, "the pure light of the void" (Evans-Wentz, 1960) to shine through. This fraction of a second may be experienced as a "mystic state," satori, a peak experience or an altered state of consciousness (Tart, 1969). It may be experienced as a moment of "fascination" or "falling in love," when the gap in one's awareness is filled by the *new* that suddenly intrudes itself.
>
> *The creative moment is thus a gap in one's habitual pattern of awareness*. Bartlett (1958) has described how the genesis of original thinking can be understood as the filling in of mental gaps. *The new that appears in creative moments is thus the basic unit of original thought and insight as well as personality change*.

> Experiencing a creative moment may be the phenomenological correlate of a critical change in the molecular structure of proteins within the brain associated with learning (Gaito, 1972) or the creation of new cell assemblies and phase sequences (Hebb, 1963.)

The relation between psychological shock and creative moments is apparent: A "psychic shock" interrupts a person's habitual associations so that something new may appear. Ideally, psychological shock sets up the conditions for a creative moment when a new insight, attitude, or behavior change may take place in the subject. Erickson (1948) has also described hypnotic trance itself as a special psychological state that effects a similar break in the patient's conscious and habitual associations so that creative learning can take place as follows (italics are ours):

> The induction and maintenance of a trance serve to provide a *special psychological state in which the patient can reassociate and reorganize his inner psychological complexities* and utilize his own capacities in a manner in accord with his own experiential life ... therapy results from an *inner resynthesis* of the patient's behavior achieved by the patient himself. It's true that direct suggestion can effect an alteration in the patient's behavior and result in a symptomatic cure, at least temporarily. However, such a "cure" is simply a response to suggestion and does not entail that reassociation and reorganization of ideas, understandings and memories so essential for actual cure. *It is this experience of reassociating and reorganizing his own experiential life that eventuates in a cure*, not the manifestation of responsive behavior which can, at best, satisfy only the observer.

Fine examples of this "reorganization" and "inner resynthesis" were later provided in Erickson's paper, "Pseudo-orientation in time as a hypnotherapeutic procedure" (1967), wherein he illustrates the approach of allowing the patient's unconscious, while in a trance state, to creatively fantasize its own solutions to problems. Erickson describes this approach as follows:

> Unconscious fantasies, however, belong to another category of psychological functioning. They are not accomplishments complete in themselves, nor are they apart from reality. Rather, they are psychological constructs in various degrees of formulation for which the unconscious stands ready, or is actually awaiting an opportunity, to make a part of reality. They are not significant merely as wishful desire but rather of actual intention at the opportune time....
>
> In these case histories, extensive emphasis was placed upon fantasies concerning the future, and every effort was made to keep them unconscious by prohibitive and inhibitive suggestions. By so doing, each patient's unconscious was provided with a wealth of formulated ideas unknown to the conscious mind. Then, in response to the innate needs and desires of the total personality, the unconscious could utilize those ideas by translating them into realities of daily life as spontaneous responsive behavior in opportune situations. (1967)

This approach is very different from the older more traditional hypnotherapeutic approach of simply telling the patient, while in the trance state, exactly in *what* way and frequently *how* the patient's attitudes, beliefs, and behavior are to change. This more traditional approach of directly programming the patient is in sharp contrast with Erickson's facilitation of new learning by allowing patients to *create their own solutions* in their own way and usually in their own good time.

But what, now, is the essence of Erickson's approach of allowing patients to create their own solutions? The author expected Erickson to agree that patients are actually synthesizing new psychic structures—(the phenomenological correlates of molecular change in the brain (Rossi, 1972)—when they are involved with their "unconscious fantasies" during the trance state where emphasis is placed upon their future hopes. Erickson, however, tends to demur over such an interpretation. He emphasizes that in the ideal psychotherapeutic situation the therapist does not add anything new to the patient but simply helps the patient rearrange and more constructively utilize *past* learnings. He does acknowledge that this rearrangement may involve the synthesis of new associative connections, however.

This issue may be illustrated by utilizing Osgood's (1957) type of diagram of the semantic relation between complexes of meanings. In Figure 1 a circle represents a meaning-complex, while lines represent the links relating the various meaning-complexes together. In Erickson's shock approach a central neurotic complex (represented, for example, by a neurotic inhibition, behavior, or attitude) is shattered (Stage 2 in Figure 1), so its related meaning-complexes are free to rearrange themselves in another more constructive manner (Stage 3a). A more encompassing view of hypnosynthesis (Conn, 1971) might represent the final situation as 3b, where a newly synthesized meaning-complex replaces the shattered central neurotic complex, permitting a better realignment as illustrated.

Apart from the patients cited above in his paper on pseudo-orientation in time (1967), Erickson has recently described a unique situation in which he appears to have fostered the development of new personality structures (newly synthesized meaning-complexes) in the case of the "February Man" which is presented as the last article in this volume (see also Erickson & Rossi, 1979). In brief, this was the case of a young woman who had grown up in a materially rich but emotionally impoverished milieu such that she was afraid to have children lest they have a childhood as "miserable and lonely" as her own. In a series of interviews Erickson used hypnosis to regress her to earlier age levels (4 or 5 to 14) during which she fully experienced and enjoyed delightful conversations with Erickson playing the part of a friendly and warm-hearted "February Man." Her experiences with the February Man soon came to embody all the happy and warm feeling and associations she had missed in her actual childhood. An amnesia was maintained for all these trance experiences, so that as therapy continued, the patient in the ordinary waking state began showing less and less concern about her possible inadequacy as a mother, and repeatedly asked Erickson what he was doing with her in the trance state to give her a feeling of confidence that she would know how to share things properly with children of all ages. Although Erickson is more modest in assessing his work in this case,

this author feels it to be of great significance, since it appears so clearly to illustrate psychotherapy as involving the synthesis of new psychic structures rather than a mere restructuring of old material. The author (1972) has recently presented in great detail a number of unusually revealing examples of the spontaneous synthesis of new personality structures in series of dreams.

This, then is a basic issue which future research and practice must resolve: Is hypnotherapy (and psychotherapy, in general) to be concerned with the actual synthesis of new psychic (and behavioral) structures, or is it basically dealing with the creative reutilization of previous learnings? It is easy enough to acknowledge that both are probably involved in practical work, but the future development of both theory and practice may be greatly accelerated by clarifying just when and exactly how each are used.

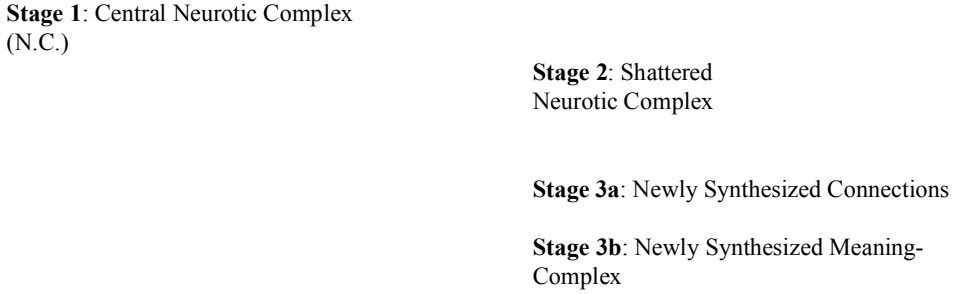

Figure 1. An outline of shock therapy (Stage 2) and creative moments (Stages 3a and b) involving - the synthesis of new connections (Stage 3a) and/or a new meaning-complex (Stage 3b).

Facilitating a New Cosmetic Frame of Reference

Milton H. Erickson

Unpublished manuscript, 1927.

A sophomore in college, majoring in home economics, sought therapy because of "awful inferiority feelings" that seriously restricted and hampered her daily adjustments. The essential facts of her history were few and easily understandable. She had experienced no personality difficulties until the onset of puberty. At that time, during a pleasure drive in the family automobile, an accident had caused her to be thrown out of the car. The only injury she had suffered was a "gashing of the right side of my mouth, which caused awful scarring. That's why I keep the right side of my mouth covered with my hand, or I turn my head away so that you can't see that side of my face." This mannerism had been noted as constantly present. She was unwilling to exhibit the scar to the writer, insisting that it would "disgust" him if he were to see it.

Additional inquiry disclosed that, although she was right-handed, she had learned to eat left-handedly in order to keep the scar covered while eating. Only in the family circle would she briefly discontinue her hiding behavior. She tolerated no mention of her disfigurement, however, by anyone. On the street, in social gatherings, or in the classroom she kept the right side of her mouth covered. She had escaped physical education in high school and college by means of a medical excuse from the family physician.

Because of her need to hide the scar, she was handicapped in numerous other ways. She could not drive a car because that would leave her face uncovered. Neither could she swim except in privacy. Everything she did was governed by her compulsive need to keep the right side of her mouth covered by either her left or her right hand. Even her association with men was markedly limited, despite her actual attractiveness. In fact, her social engagements with men were limited to walking on the man's right side in the dark. On such walks she would not smoke, although she enjoyed smoking, for fear that the glowing of the cigarette would light up her face. However, she would permit kissing, which she enjoyed very much, providing the darkness was deep enough.

Many efforts had been made to have her wear special cosmetics, since she was "so sensitive about a little scar." This she refused to do; why, she did not know. On her own initiative she had visited a number of plastic surgeons, since her parents had "always taken a completely unreasonable attitude" about the scar. However, all three plastic surgeons had taken "the same unreasonable and unsympathetic attitude my parents took." The result was that she had intensely hostile feelings toward the medical profession.

The rest of her history was not indicative of any other problems, although it illustrated many more of her handicaps in daily behavior. Essentially, her situation was that of a

young girl with one arm paralyzed and held in an awkward position covering her scar. Her object in seeking therapy was to learn how to adjust to her handicap without correcting her behavior. She was not receptive to any ideas about the possibility of altering her understandings about the "awful scar."

Not until the third interview would she permit the writer to see the scar. It was examined at great length but without comment. Finally, her extreme tension was relieved by telling her that she might again cover it with her hand and keep it covered.

CONCRETE DISPLACEMENT OF SYMPTOM

During the taking of her history it had been learned that she had considerable talent in sketching, in which she took a great deal of pride. Accordingly, she was given the assignment of going home and, in the privacy of her room, making a life-size sketch of her face, showing the exact position, shape, and size of the scar. This was to be done with every possible attention to the minutest details, and the sketch was to be "true to life and scientifically accurate."

When she succeeded in producing a sketch that she was confident was "accurate and true," she was to bring it to the writer. If she wished, she could bring it in a sealed envelope that would not be opened until she was sure that she was willing for the writer to examine it. She spent the rest of that day and a good share of the night perfecting the sketch, which she brought to the writer in a large, unsealed manila envelope. Since she expressed full willingness, a hasty glance was taken at the sketch, and it was then replaced in the envelope and filed in her case history folder. It was noted that she still kept the scar hidden but that she was much less tense and anxious. Instead, she appeared much bewildered and puzzled.

TRANCE INDUCTION AND POSTHYPNOTIC SUGGESTION

She had previously refused to permit hypnosis, but she now readily accepted the suggestion that a trance should be induced so that she could be given a new, different, and unrelated assignment. A fairly deep trance was readily induced, during which she kept her left hand over the scar. Her next assignment, she was told, was twofold. She was to visit the college library, consult her mother, inquire of fashion experts, or consult any possible source she could discover to learn everything possible about the old-time practice of applying "beauty patches." This done, she was to make a series of sketches of women's faces showing the various shapes and locations of beauty patches. All of this was to be done in the waking state, but with no conscious awareness of why she was doing it. Nevertheless, she should know that she was doing it and wonder why. When the task was comprehensively done, she would decide to show the sketches to the writer. Each sketch would be similar to the self-portrait she had executed, and each would illustrate the use of a single beauty patch. She was then awakened with an amnesia for the trance events.

SHOCK AND SURPRISE: CONFLICTING FRAMES OF REFERENCE

About two weeks later she appeared with a collection of sketches amply illustrating shapes, sizes, and locations of beauty patches. She was intensely puzzled and curious about the overwhelming interest she had experienced in executing this assignment. She was asked to exhibit the sketches and to discuss them. Fortunately, all these sketches were on sheets of paper the same size as her first drawing, and all the feminine faces she had drawn were similar in outline to her self-portrait.

Advantage was taken of this to run hastily through the drawings, asking a simple question concerning each, and then to slip into the pile her self-portrait. She was then asked to scatter them over the table and to identify each particular type of beauty patch, whether a crescent, a star, a diamond, or whatever, and to give the reason for the site of application.

So engrossed did she become in this that she failed to recognize immediately the self-portrait. Instead, she described the scar as a six-pointed-star-shaped beauty patch applied to the corner of the mouth to attract attention to that feature as one most attractive. The fact that it was six-pointed instead of five-pointed puzzled her, and she expressed her surprise because she was certain she had only drawn five-pointed stars. As she puzzled over and examined the drawing further, she finally recognized it, with a sense of shock, as the self-portrait. For the next five minutes she faltered in her speech and stammered fragmentary utterances as she strove to integrate two conflicting frames of reference—the one centering about her "awful, disfiguring scar," and the other, her six-pointed-star-shaped beauty patch properly placed in relation to her definitely attractive mouth.

REINFORCING THE NEW FRAME OF REFERENCE

Finally, as she sat there, helpless in the face of her new understanding of her scar, she was told:

> Your parents, your brother, your friends were all so "unreasonable" as to think that your scar was just a beauty patch. The plastic surgeons thought so, too, and brushed you off as a silly girl who refused to recognize the scar for what it was. I, too, am sufficiently unreasonable as to see that scar as a little white star-shaped beauty patch at the corner of a very pretty mouth. *And you yourself—in fear, distress, abhorrence—drew your portrait accurately and well, and without knowing it you portrayed that scar for what it was, a beauty patch which, unguardedly, you recognized correctly*.
>
> Now, let's be scientific about this. Beauty patches are intended to draw attention to the most attractive feature. You have pretty eyes, you have a pretty dimple in your left cheek, you have a pretty mouth. You like to be kissed, and a number of boys have kissed you. Go out with them again, one by one. Let them kiss you goodnight under the porch light. Make a mental note of where they kiss you, on the left side of your mouth, full face, or on the right side. I think they will kiss the side with the beauty patch. *You will find out*.

Now, go home, take these sketches—all of them—with you. You did them carefully and well. You learned a tremendous amount from them. You can keep the sketches, or you can give them away. *But what you learned from them you will always keep*.

SYMPTOM RESOLUTION AND SIX-YEAR FOLLOW-UP

Subsequently, she reported that she was invariably kissed on the right side of her mouth. (The objectivity of this report is open to serious question, however.) Moreover, she rapidly freed herself from the habit of covering her mouth and lost her feelings of inferiority. She married two years later and now has four children.

The Ugly Duckling: Transforming the Self-Image

Milton H. Erickson

Unpublished manuscript, 1933.

Two young women, high school classmates but not friends, were in love with the same young man. One girl was rigid and prudish; the other girl, was decidedly permissive. When the latter was about three months pregnant, she and the young man were married. Three years later the man divorced his wife for adequate reasons, and two years later he married the other girl. A baby girl was born to them two years later, much to the father's delight.

The marriage continued reasonably happy with one exception. The mother was much too puritanical with the daughter, who at the age of 25, became the writer's patient. The daughter sought psychiatric help because her marriage of four years' duration was becoming seriously unhappy. Her story was to the effect that her husband was an "intolerable, unspeakable liar," and had been since she first met him. She had excused him during their courtship and for the first year of married life because "you have to take what a man says when he is in love with lots of salt." Now, however, because her son was almost three years old and beginning to understand many things, she did not want his father "constantly telling lies."

Many times she had tried to discuss the lying with her husband but found herself unable to do so because he was "so sweet and loving" and because "I suppose I wish his lies were true. I can't help it." Nevertheless, within the past year she had become so tense and so irritable and so unable to discuss anything with her husband that she had been resorting to unprovoked temper tantrums, outbursts of screaming, threats of divorce, and ideas of suicide. At no time had she been able to discuss her husband's lying with anybody, and only his insistence that she consult a psychiatrist resulted finally in her call on the writer.

A previous visit from her husband disclosed him to be much alarmed about his wife's mental state, since he could only describe her sudden outbursts of violent temper and hex bouts of weeping, which she apparently could not explain to him. He knew of no provocation whatever and considered the marriage otherwise a happy one.

The patient was most unwilling to reveal what lies her husband told so repetitiously, insisting that the writer need only instruct her husband to tell the bare, simple truth. Finally, after extensive persuasion, she agreed to inform the writer. In effect, her husband, because he was in love with her as a person, out of the mistaken goodness and greatness of his love, insisted on telling her that she was pretty, that she was cute, that her hair was lovely, that he liked the tilt of her nose, "and all those silly things that men, when they fall in love, say."

She went on to state that ever since she was a tiny child her mother had "daily" told her that she was homely and unattractive, that her lack of beauty was a cross she would have to bear cheerfully and gladly. In addition, it would be only right and good for her to develop a charming personality, since that would last a lifetime, while beauty always faded away.

As a small child she had not been much concerned about her looks. In high school she had developed considerable self-consciousness, but had finally resigned herself to her fate and enjoyed "exercising her personality." She seldom accepted a second or third invitation from the high school boys because they "lied" to her about her looks. Following graduation she had obtained a secretarial job, which she continued until her marriage.

Her first social engagement with the man she married had impressed her indelibly. He had told her then that she had the most charming personality that he had ever encountered. This had been reiterated during subsequent engagements, and not until later had he told her how pretty she was. She had accepted these compliments then because he was in love with her and because they were in accord with his response to her personality. Therefore, his "lies" could be forgiven as emotional exaggerations.

With the advent of pregnancy, however, her nipples had become very deeply pigmented. Her mother had informed her that child-bearing always cost a woman whatever little beauty she had. The daughter's reaction was one of acceptance of "that fact" and strong resentment toward her mother. Thereafter, visits at the maternal home became much less frequent, and finally, they were limited to holidays and family anniversaries.

Her husband, however, had not manifested any dislike for the nipple pigmentation. In fact, he had "falsely acted pleased" about it. This, coupled with his continued expressions of his regard for her "beauty," had placed her in the unbearable situation of being constantly reminded by his compliments of her misfortune and his mendacity. She felt that a solution to her problem would be a straightforward, open, honest recognition of the fact of her unloveliness. Then the question could be dropped, and no further references need ever be made to her looks.

A careful attempt was made to get her to evaluate her features one by one, since, to the writer as well as to her husband, her features were better than averagely attractive. Her ideas were rigidly fixed, however, and she promptly accused the writer of trying to gloss over her lack of beauty to pacify her. Accordingly, the effort was abandoned. Despite her impatience about the writer's interest in "irrelevant matters," inquiry disclosed no other significant problem. Her son was described as the "spitting image" of his father. "You can tell them apart because Johnny doesn't have a moustache."

When questioned about the possibility that her husband might actually believe that she were pretty, since "people often tell lies until they actually believe them," she was rather nonplussed. After some thinking she stated that, if such were the case, therapy might help

her to tolerate the situation better, so that she would not lose her temper and become so depressed by his mistaken beliefs.

THERAPEUTIC TRANCE, EXPECTANCE, AND INNER SEARCH

Since she was aware, through another patient, of the writer's use of hypnosis, it was a relatively easy task to interest her in hypnotherapy. She was a good subject, required little training, and was most cooperative. As the first measure, although extensive inquiries had been made previously of her husband, she was asked to list the various nursery tales she read to her son and to the six-year-old neighbor girl for whom she often cared on weekends. Among the tales was one she read with great frequency, "The Ugly Duckling." She was asked to recite in the trance state a number of the stories, among them "The Ugly Duckling." No special attention was apparently given the story by the writer. However, her husband stated that she had read the "Ugly Duckling" story to her son frequently since about his second birthday.

At the next session she was told in the trance state to discuss her husband's heavy, dark-brown moustache. She expressed great admiration for it, repeated how she insisted that he grow one, since it would make him look distinguished, and had refused to let him shave it off. During their courtship she had insisted that he grow one, and he had done so. Still in the trance state, she was instructed as a posthypnotic task to take a heavy, dark-brown eyebrow pencil and to paint a moustache on her son as a practical joke on her husband. Then, after they had finished laughing at it, she was to examine it and her husband's moustache and to learn to understand something of great importance to her. What this was she would not know at first, but at the right time it would become fully understood—with tremendous force.

At the next session she was to relate her reaction to the moustache on her son. In effect, she described it as a "hideous thing" since it did not "fit" on Johnny's face, even though a moustache looked so well on his father, and despite the practically identical facial appearance of father and son. She also expressed feelings of a vague inner unrest, as if she were trying to understand something she already knew.

She was then hypnotized deeply and told that her unconscious was to remember a nursery tale and to think that tale over without letting her conscious mind know about it in any way. This nursery tale would be selected by her unconscious because it would apply to her in a most peculiar way and would fulfill her need to understand adequately certain things she had to know about herself. Furthermore, she would have to search through the nursery tales with which she was acquainted, that none of them would seem to her the right one, but that she would finally give up the task of searching and just take the handiest one, hoping that it would be the right one. Several days would have to be spent by her unconscious in its study of the tale. Also, she would probably dream about it, happy dreams, but she would not remember her dreams. Neither would her unconscious let her know what it was thinking about. Nevertheless, she would be consciously aware that something was happening within her, altering her attitudes and understandings.

At the same time, in some way, the moustache painted on her son's face, so hideous to her and so out of keeping with his face, and her husband's moustache, so attractive on him, would fit into the nursery tale in some way that would clarify all of her thinking and establish those attitudes she so greatly wanted.

Finally, just before her next session, she was to be unconsciously impelled to do something that would inform the writer, immediately as she entered the office, that her unconscious had completed its tasks adequately. Then, during the session, either in the waking or the trance state, she would begin to discuss with increasing understanding her new, altered, unconscious understandings, and thus make them a part of her total life reactions and attitudes.

She was seen five days later. She apologized as she entered the office for being late, explaining that she had been detained at the beauty shop where she had "blown the works." She added that in the past she disliked going to beauty shops and had never had more than a permanent wave, but this time she had had everything they could offer. No comment was made except to state that she really could "follow orders." This puzzled her, but she began a casual conversation, suddenly interrupting to state that she wanted to talk about the moustache she had painted on her son and about her husband's moustache.

She was told to think over the topic carefully and to organize her thoughts. After a few minutes she began, explaining in effect that she had duplicated on her son's face a replica of her husband's moustache, in smaller size but of the same dark-brown color and shape. The effect had been grotesque and hideous because it did not "fit." The boy was too small, his appearance was too young, and hence, despite his extreme resemblance to his father, the result was a distasteful mockery. Only when he became old enough and mature enough would the dark-brown color on his upper lip be attractive.

She paused, blushed, and impulsively declared, "It's just like nipples." A further pause, "A girl's nipples should look young, but when she has matured and been pregnant, they really should look different. Why, it would be like a grownup man who had a boy's skin on his face. It wouldn't look good." After a pause she added, "Maybe I better stop trying to look at myself as if I was a little girl. My husband sees me grown up."

This observation elicited a startled silence in her. Then again she began, "I've just thought of `The Ugly Duckling' story. All my life I've read that story over and over. I never knew why. And the last few days I've been so absentminded. I've just been keeping that story in the back of my mind. Do you know, I bet those old ducks still think that that swan is ugly. It had to join the swans to find out that it was beautiful."

Reply was made, "The old mother duck will always think the young swan is ugly, but what will the other young swans think? And what will the young swan really know about itself?" Before she could reply, she was told emphatically, "You know and you will always know."

“And now, when your husband comes home tonight, why don’t you cuddle up to him at the door and ask him simply, immediately, ‘Don’t you want to take a pretty girl out to dinner tonight?’”

“Your next appointment will be in one week’s time at the same hour.”

Thereupon she was summarily dismissed.

Her husband was seen before she was. He reported that she had obeyed instructions exactly and that he had been so astonished that he had forgotten a business appointment and enthusiastically agreed to her suggestion. He was most emphatic about the transformation in his wife, expressed curiosity about what had happened, but agreed to await such time as she chose to discuss the events of therapy.

At her interview the discussion was kept on a vague, casual level. About three months later she asked for an appointment. The purpose was to discuss any possible need to inform her husband of her original “silly ideas.” Inquiry disclosed that he had apparently lost all curiosity. A year has passed. They were seen again because they brought to the writer a young couple, intimate friends of theirs, who were considering divorce because of marital problems, and they wished the writer to handle that problem as well as he had handled hers. Inquiry disclosed them to have been adjusting most happily.

A Shocking Breakout of a Mother Domination

Milton H. Erickson

Previously unpublished manuscript, circa 1936.

Dr. X received over 300 hours of intensive psychoanalytic therapy by the past president of the American Psychoanalytic Association and of the International Psychoanalytic Association. This therapy had been without any therapeutic results. He was then taken over as a patient by another past president of the American Psychoanalytic Association and underwent another 300 hours of intensive psychoanalytic therapy with no results. He was then referred to the author.

CONSCIOUS LIMITATIONS AND HYSTERICAL DEAFNESS

About six hours were spent determining the fact that there was no approach to him to be made at the conscious level. He could narrate his obsessional fears, doubts, and compulsions, but if any comment of any sort were made to him during the hour, his eyes would glaze over, and it was entirely obvious that he would develop a hysterical deafness. This was tested by sounds that should have elicited startle reactions. Apparatus had been rigged so that a sound could be produced behind him, so there would be no possible visual awareness of what was about to happen. He made no startle or response of any kind to these unexpected sounds. It was found, however, that he would maintain sufficient visual awareness and sufficient selective hearing that he could hear and understand when the author was not speaking about him as a patient.

TRANCE INDUCTION AND TRAINING FOR POSTHYPNOTIC SUGGESTION

Having made these determinations, in the next two hours he was given the explanation that he would be hypnotized, and no effort of any sort would be made to do therapy, that every effort would be spent in training him to be a good hypnotic subject. To this he agreed readily in the same passive, accepting manner in which he had come for therapy. He entered into a deep somnambulistic trance quite readily, and a considerable amount of time was spent in teaching him to experience the various hypnotic phenomena, particularly the execution of posthypnotic suggestion. These were of great variety, but there was a careful avoidance of anything that might be construed as therapeutic. At a later date, during a three-hour session, a deep somnambulistic trance was induced, and there was a systematic presentation to him of a long series of posthypnotic suggestions. These were explained as suggestions that he would not have to execute during the trance; that they would be without therapeutic effect in the trance; that they were posthypnotic suggestions that would be carried out at a later date in a situation far removed from the author's office and at a time when he and all others would recognize him as in the

conscious state. Interwoven with these suggestions was the reassurance that he need not be afraid of listening to these posthypnotic suggestions, that he could comfort himself by knowing that, as he listened to them, they were without effect upon him as a person and as a personality; that they could have no significance until some time in what would seem to be the remote future. An example was drawn for him to the effect that he could readily accept the suggestion here and now; that two weeks from now, on a specified date, he would eat a beefsteak and that in no way need he reject that possibility. Similar parallels were drawn to ensure his full understanding that he could accept all posthypnotic suggestions and merely thoughtlessly postpone their effectiveness to what would seem to him to be the remote future.

These posthypnotic suggestions had been worked out with a great deal of care, and they were developed on the basis of the information given to the author by the patient's wife, an intelligent, cooperative, long-forebearing person who had endured her unhappy lot without complaint.

In essence the situation was that he was completely ruled by his mother. He and his wife had been married 15 years. The parents had given him and his wife a house alongside of theirs. The bride and groom had not been permitted to go on a honeymoon. His mother had insisted that he take two weeks off from his practice and honeymoon in their new home. To the bride's horror the groom's mother showed up in her kitchen the next morning to prepare breakfast. She had decided on the menu, and the bride and groom had to eat what she cooked. Mother also prepared lunch and the evening meal, besides telling them when to go to bed and when to get up. This type of behavior on the part of the husband's mother had continued for the entire 15 years of their marriage. Mother took them to church and made them sit in the pew with the young husband next to his mother and separated from his wife by his father. Mother took them out to dinner at her favorite places. Mother took them to her choice of places of entertainment. In brief, in the entire 15 years of that marriage the mother had dominated every detail of their home.

Mother belonged to the Woman's Christian Temperance Union and during medical school when he lived in the fraternity house, Sonny had imbibed alcoholic beverages. He had never dared tell his mother, and at least once a week she delivered a sermon on the evils of alcohol. Neither was he allowed to drink soft drinks, tea, or coffee. He had once ventured to request the privilege of drinking buttermilk, but his mother had expounded on the virtues of drinking only water and pasteurized milk.

Mother picked out his shirts, his ties, his shoes, and his underwear; she specified every change of clothing down to which suit he was to wear on which occasion. Mother did permit him to go to the office unescorted. But on any other trips away from home she went with him and handled him as if he were around the age of three of four years. Initially in his married life he had walked to his office; Mother said the exercise was good. But after the first year he began to leave early in the morning to avoid having people see him alone on the streets. His mother approved of long hours spent in the office, and he began working late at night in order to avoid being seen; this was not too effective, however so he began coming home by way of alleys.

In his practice of medicine he was engaged in a specialty that permitted the minimum of contact with his patients, most of whom were seen by his office help and technicians. His mother insisted that he go to medical meetings, but she always escorted him there and back. Very promptly he became too self-conscious to participate in any activities of the county medical society. In fact, he began avoiding speaking to his fellow physicians. After 12 years of this he sought therapy, and his parents begged for a special, private room at the institution where he was treated. His mother took lodgings nearby, was permitted to visit him daily and took him for walks, so that he did not participate in any of the institutional activities for patients. Since he made no improvement after over 300 hours, his mother decided to seek another therapist; she escorted him to that therapist's office and accompanied him back home. This the therapist permitted.

When Sonny was brought to the author for therapy, Mother was told in most emphatic terms that she could not accompany him to the office, that she would have to delegate that responsibility to his wife. The author finally succeeded in conveying to the mother the idea that forcing the wife to bring her husband to therapy would be an appropriate punishment for the wife, and that she in her earnest solicitude for her son's welfare should see to it that his wife undertook the punitive duty of bringing her husband for therapy.

The interview with the wife after this hoax had been perpetrated upon the mother was most delightful. She was an intelligent, capable young woman who felt herself hopelessly lost in dealing with her mother-in-law and incapable of weaning her husband away from her. It was possible to talk to her freely and frankly and to secure her promise of secrecy about the author's plans. In fact, she was most delighted with the author's intentions and most enthusiastic about cooperating. She was told to let Mother continue her domination unabated but to look forward with mirthful anticipation to what was going to happen to Mother.

The posthypnotic suggestion given to the patient in the deep trance had been worked out in extensive detail, and the patient's wife had been consulted extensively to ensure its completeness. The explanation was given to the wife that the patient could not accept therapy in the ordinary waking state and that he did not accept it in the trance state. The approach employed was to use hypnosis to impress thoroughly upon the patient's mind all the things that would lead to therapy in the trance state, but with the suggestion that they would be inoperative in that trance state. He was told that all therapeutic suggestions would become uncontrollably effective at a specified date in the future when he was in the state of full conscious awareness. In other words, the therapy was given in the trance state but remained inoperative until some later time of full conscious awareness, at which point it would become compulsively effective.

A SHOCKING BREAKOUT OF A MOTHER DOMINATION

When all of the posthypnotic suggestions had been completed, a specific date and a specific hour was set; namely, 10:00 A.M. on Sunday morning, the hour at which the

mother always came to take her son, his wife, and their two children to church. That morning mother had already prepared breakfast for her son and his family and had gone home to dress for church. Her son and his wife and family had also dressed for church. The mother came in, and her son greeted her as usual; then as related by his wife, in full agreement with posthypnotic suggestion, the son said, "Mother, would you please come into the kitchen for a minute?" His mother wonderingly followed him. He walked over to one of the kitchen shelves, took down a bottle of whiskey that was only partially corked so that he could remove the cork easily, and poured out a glassful while his mother stood in shocked, silent horror; then, with a stream of profane and obscene expletives, he declared his intention to get drunker than a lord, and that she was to haul her f—a— to church without him—whereupon he promptly drank six ounces of straight whiskey. What the patient did not remember was that immediately after breakfast he had gone to the bathroom, had inserted his finger in his throat, and had vomited up his entire breakfast. The impact of the six ounces of straight 100 proof whiskey was most startling, and it was added to by the posthypnotic suggestion. He collapsed on the floor; his wife and his mother undressed him and put him to bed, while he sang some unexpurgated songs dating back to his fraternity days; then he collapsed in a drunken stupor. His mother was so horrified that she went home and took a bath, having missed church for the first time in many many years.

She remained in bed until the next morning, when she came over to fix breakfast. As she came in, she found her son awaiting her in the breakfast room. He greeted her most profanely and obscenely, explaining, "I have been waiting for you because I am thirsty for another drink of whiskey," and thereupon he drained a glass of what appeared to be whiskey. Actually, it was tea prepared by his wife to look like whiskey. Having drained the glass, he said, "Now I had better stagger off to bed," and he began singing, "Drunk today, drunk tonight, drunker than I have ever been before." His mother left in tears and went to bed for the day and night. As soon as his mother was safely out of the house, one of the children kept watch in case the mother or father should appear. The man's wife prepared the first breakfast she ever had in 15 years of their married life. The patient notified his office that he was indisposed and he would not be in that day. At noon the patient's wife prepared lunch, and that evening, the dinner. They went to bed at the hour of their choosing. In all of this the patient's wife played a passive, submissive role in relation to her husband just as she had to her husband's mother, and in response to posthypnotic suggestion the husband began to rejoice in his wife's attitude toward him. The next morning the mother stalked into the house and said she was going to clean it out. She saw the whiskey bottle actually filled with tea and dumped it into the sink. She found another bottle of whiskey that had not been opened, and she rejoiced mightily in opening it and draining it down the sink. Then she ordered her son to march into the living room to listen to her while she "explained a few things." She also demanded that his wife and children do likewise. Very meekly the patient did as told, and as the mother began, "Now you listen to me," her son pulled out a half-pint flask of actual whiskey and drained it before his mother recovered her poise sufficiently to rush at him and take it away. The wife had immediately seized the two children aged 12 and 10 and rushed them out of the room. The patient profanely and obscenely told his mother that if she ever again came into the house without an invitation, he would promptly get

drunk, and that he might even ask his wife to get drunk with him. He then ordered her with much vulgar language to get out of the house, saying that if she dared to call any physicians or any friends to come to see him, he would take extremely unpleasant measures against her.

Mother left rather frightened. For the next three months she did not appear, but her son noted that she was watching out of an upstairs window to see if he went to the office and if he was walking home. During those three months the man and his wife established a good understanding of the total situation. Also, during those three months the patient came alone to see the author to have his posthypnotic suggestions reinforced and still further elaborated. At the end of three months a new set of instructions was given the patient. He was to locate a house that he would like to live in; to make arrangements either to rent or purchase it; and then to make arrangements with the moving company to be completely moved into the new home on the other side of town during one of his parent's periodic day-long visits to an out-of-town relative.

The patient and his wife spent six weeks locating a desirable house and making appropriate arrangements with the moving company. Upon the mother's return in the evening of the day of the moving, she was utterly astonished to find a vacant house where her son had lived.

She appeared at the office the next day to find out the location of his new home. He told her coldly that he did not think she should know, and if she tried in any way to find out, he and his wife and her grandchildren would never again visit her. Greatly subdued, the mother left and made no further attempts to intrude upon her son's life.

A year later the son and his wife made a formal call on his parents, and good family relations were established. At Thanksgiving dinner the mother started to tell him what he should have on his plate and to her utter horror she saw her son, her daughter-in-law, and their two children leave the table and go home. However, they appeared for Christmas dinner, and the mother behaved herself. Thereafter good family relations were established, which the son carefully tested by offering his mother a glass of whiskey—which she politely refused—while he and his wife drank in her presence.

All together a total of not over 20 hours were spent working with this patient. (The author did not find that the previous 600 hours of psychoanalytic therapy had aided the patient's breakout in any way.) In addition to his healthy family adjustment, the patient began to participate in county medical society meetings, was elected president of the county medical society, was elected president of the state medical society, and later was elected to office in the national society of his specialty.

Shock and Surprise Facilitating a New Self-Image

Milton H. Erickson

Unpublished manuscript, circa 1930s.

The purpose of psychotherapy is to enable a patient to achieve a legitimate personal goal as advantageously as is possible. Properly, it is not a matter of advancing particular schools of thought or of attempting to substantiate interpretative psychological theories, but simply a task of appraising a patient's problem or problems in terms of the reality in which the patient lives and in the terms of the realities of the patient's continuing future as he or she may reasonably hope for it to be.

The author is well aware that this brief formulation of psychotherapy and its purposes is in marked contrast to those schools of psychotherapy which insist that, as a prerequisite for future adjustment, a painstaking, laborious one-to-three-year-or-more minute scrutiny and analysis be made of the long-dead and unchangeable past before even touching upon the patient's actual present and future needs, understandings, capabilities, and possibilities.

Yet one may consider the few troubled people who are benefited by psychotherapy of all kinds and the countless numbers who, while also having problems, still succeed without therapy in achieving goals that they and others regard as constituting real personal and social success. Thus, after such consideration, one may well wonder at the self-reassuring dogmatism of the many self-styled "the one-and-only right" schools of interpretative, speculative psychotherapy.

After this somewhat acrimonious introduction the author wishes to present a case history in which there was employed successful psychotherapy caustically described by some colleagues as "unorthodox and not in accordance with established rules of psychotherapy." The fact that the patients had benefited was not considered to be pertinent to the issue by those critics.

CASE 1

The first patient was a 35-year-old professionally trained woman with a master's degree. She was very slightly overweight but otherwise was decidedly attractive, graceful, and possessed of a most pleasing personality. Her major defect can be summarized in the outraged statement of an unmarried man of her own age, holder of a doctoral degree in a field of work related to hers: "If that damned girl would comb her hair, wash her ears and neck, put on a dress that didn't look like an ill-fitting gunnysack, straighten her stockings, and polish her shoes, I could get seriously interested in her."

In summary, her appearance epitomized her problem, and the above outraged statement described her appearance very well. Yet Ann was a highly intelligent young woman, and in the author's six months of professional contact with her, he had been much impressed with the clarity and lucidity of her thinking and with her ability in the comprehensive appraisal of problems. The author had also developed an earnest respect for her competence as revealed in staff conferences; however, it was also noted that Ann had neither casual nor intimate friends, with the exception of one exceedingly competent, very friendly older woman who was quite obese and who suffered from arthritis.

Finally this older woman approached the author and explained that Ann was seriously depressed and definitely suicidal despite her outward facade of a comfortable, businesslike adjustment. She explained that for a long time she had attempted to coax Ann to seek therapy, and that only recently had Ann rather unwillingly agreed to see the author—but only briefly since, to quote her friend, "The darned idiot sees no hope for herself, and I want you to take her by the scruff of the neck and shove her face into a mirror and make her take a good look at herself as a real person of value. Nobody, just nobody—not even me—can talk to her; Ann just freezes and gets deaf and blind, and you lose all contact with her. But I finally have managed to make her listen long enough so that she has agreed to see you for a 'few times,' if you are willing. Please, for my sake, see her because I'm frightened by Ann's desperation."

PREPARATION FOR TRANCE INDUCTION

Ann appeared for her appointment with obvious reluctance. She was asked to take a seat beside the office door while the author sat on the opposite side of the room. She was told: "As you know, Ann, I'm very definitely crippled by anterior poliomyelitis, and anytime you want to escape from this office, you can get out of the door long before I can cross the room. Therefore you can feel safe here. And if you decide to develop hypnotic trances here, you will still have time to arouse from the trance state and get out of the office before I can cross the room. At the staff lecture on hypnosis, and at the demonstration which I gave recently and which you attended, I mentioned that several persons had unwittingly gone into and come out of hypnosis, and I refused to identify them. You, Ann, were one of those persons. Hence, I am delighted to see you here, and I hope you have come for the therapy that both Agnes and I think you need. However, therapy will not be forced on you. Agnes made this appointment for you. It will be used only to outline the situation. Your appearance here indicates that you recognize your need for therapy.

"Next, Agnes has told me that despite your salary and lack of any dependents you have so misused your income that in 12 years time you have saved only $700, and hence you are convinced that you cannot afford therapy. Let's correct your ideas on that at once. There is no charge for this interview. It is a courtesy to our friend Agnes, not a debt incurred by you.

"Subsequent interviews with you, if any, will be therapeutic, and they are to be paid for on my terms, and my terms only. These terms are absolute, full, and complete obedience

in relation to every instruction I give you regardless of what I order or demand. Your one and only protection from this arbitrariness on my part is that you are free to relate everything or anything you wish to Agnes first before you act upon my instructions. If she approves, you then have no choice but to obey.

"You have told Agnes you have no time for therapy. I shall, therefore, expect the most expeditious of responses from you. No dilly-dallying, no shilly-shallying. You will be told what to do, and you will do it. That's it! If I tell you to resign your position, you will resign. If I tell you to eat fresh garlic cloves for breakfast, you will eat them. I have spoken clearly and understandably. Just as clearly do I want it understood that in psychotherapy for you, I want action and response—not words, ideas, theories, concepts. I want responses, desirable, good, informative responses of action and change, not contemplation of change, but change and action of a constructive sort. If this is understood by you, let me know and I will continue.

Ann meekly nodded her head affirmatively.

"Fine! Now listen and listen well. Think over all I have said carefully for the next three days. Understand well that for the next three long days you are to think over everything that I have said to you. If I tell you to go into a hypnotic trance, you will do so. And you and I both know, I from observation, you from your unconscious learnings and actual responses in a recent staff situation, that you can respond most adequately hypnotically. I do not care if you like that frank statement of fact or not. But you want therapy, and you have so indicated in many ways, especially to Agnes.

"After the three days you are, if you decide affirmatively for therapy, to return here for that therapy best suiting you as a potentially happy, well-adjusted person. Come at this hour prepared to stay as long as I wish, and bring your checkbook with you. Discuss this entire matter with nobody, not even Agnes, who has been told to discuss your therapeutic wishes no longer. Come prepared for and committed to therapy and to the loss of your bank account and your personality problems, but don't come back if you are not so committed. The decision must be entirely yours.

"Bear in mind that therapy is going to meet your wishes, but it will not always be comfortable and easy. You want it done rapidly, and it will be done rapidly and thoroughly. Once you come, you are committed to therapy, and your bank account belongs to me as does the registration certificate for your car, whether in my possession or not. I will tell you what to do and how to do it, and you are to be a most obedient patient, learning fully to put into action all the ideas presented by you.

"Now go home; you have a vital decision to make. Do it by yourself. If in the affirmative, return in three days at this hour, with your time my time. Goodbye.

Agnes reported that Ann went through a remarkably silent, distraught three days and that her work suffered greatly.

A SURPRISING AND RAPID TRANCE INDUCTION

Ann returned at the appointed time, entered the office hesitantly and tremulously, and stood waiting for the author to speak. She was told, "Close the door, sit down in that chair near the door, and in the process of doing those two tasks develop a deep somnambulistic trance in which you will give me your full attention mentally as well as visually and auditorily. Nod your head when you feel that you are ready for me to begin."

Moments after she seated herself, Ann began nodding her head in the typical perseverative fashion of the deep trance, her gaze fixed rigidly on the author. Her blink and swallowing reflexes were absent, and her rigid facial expression was characteristic of the somnambulistic state.

"That's fine, Ann. Continue to remain in the trance as you are now. Be receptive of everything I say. Remember you are at liberty to question Agnes on any detail that you wish, but otherwise what I say remains confidential. What I am going to say to you is not something you will expect. It will be helpful, drastically so. I will outline a course of behavior for you, and this you are to execute without fail. Do you give me your absolute promise?"

Slowly, perseveratively, Ann nodded her head.

"Are you afraid?"

Ann nodded her head affirmatively.

"You need not be afraid. I'm going to startle you greatly, and I am going to give you sharp psychological pain. Both experiences will be almost paralyzingly unpleasant, and then, as you incorporate the understandings that they signify, the pain and distress will disappear. Are you ready?"

Ann nodded her head. She was told to stand with her feet close together and her hands at her side and not to move unless there arose a good indication for moving.

As she stood waiting expectantly, the author stated, "Ann, you are 35 years old; you look at least five years or more younger than you are; you are definitely attractive in appearance; you have not had a date for at least 14 years despite your pleasing appearance, personality, and good intelligence; you are five feet three inches tall, and you weigh about 130 pounds; you have trim ankles, an excellent figure, a beautiful mouth and beautiful eyes. All this you can verify yourself."

Then in a tone of voice of utter intensity, in the manner of conveying a vitally important message, she was asked the following question: "Ann, did you know that you have a pretty patch of fur between your legs?"

For some minutes Ann stood staring at the author, blushing deeply and continuously, apparently too cataleptic to close her eyes or to move in any way.

"You really have, Ann, and it is definitely darker than the hair on your head. Now at least an hour before your bedtime, let us say at nine o'clock tonight, after you take your shower, stand in the nude before the full-length mirror in your bedroom. Carefully, systematically, thoroughly examine your body from the waist down. Be pleased with your belly button, curious about that pad of fat between your belly button and your pretty pubic hair.

"Try to realize how much you would like to have the right man caress your pretty pubic hair and your softly rounded belly. Think of how you would like to have him caress your thighs and hips. Stand there in front of the mirror and keep standing there until you have realized all of this. Then, as you become pleasingly tired physically, go to bed happy, blushingly happy, knowing that you do have a pretty piece of fur between your legs, and fall restfully into physiological sleep, and sleep restfully the whole night. You do not need to remember your dreams, nor will they disturb your sleep; but the next day, outwardly calm and composed but inwardly warm and happy, work well and comfortably.

"Do you understand all of this instruction, and are you prepared to do it as I have outlined it? Nod your head affirmative if you understand fully:"

Slowly Ann nodded her head, continuing to blush constantly and to breathe irregularly.

"Now listen carefully, Ann. Shortly you are to awaken from your trance. You are to have a complete amnesia for all that has happened here, has been said here, has been experienced by you here. Go home, take your tub bath or shower early, dry yourself, then suddenly find yourself standing in front of your full-length mirror, staring at yourself from the waist down, and then remember in full detail everything that was said to you here, every comment, every instruction; and, Ann, execute them fully. This you will do to the full satisfaction of my instructions and to the full satisfaction of your needful understandings of the therapeutic advances you need to make.

"Then tomorrow, at this same hour, come for your second appointment. Come dressed as you are today, in the same dress, outwardly appearing exactly as you do today. Now arouse from your trance with the total amnesia I have asked for and go about your duties, unconsciously awaiting the right time tonight. And in the process of arousing gently, sit down comfortably in the chair there and then become fully alert but not curious because I dismiss you."

Ann sat down, obviously aroused from her trance state, and looked expectantly at the author. She was told not to be curious about the passage of time (she had looked at her watch and had showed marked astonishment), that all was well and that she would, without further instruction, keep her next appointment. With a most puzzled look she departed.

She appeared a half-hour early for her next appointment, but spent that extra time pacing back and forth in front of the office as if attempting to make up her mind whether or not to keep her appointment. Exactly on time she entered the office, her face bursting red with blushes. Precipitously she declared, “I remember everything. I don’t know what to say.”

“Just close the door and sit down in that chair.”

She did so, immediately developed a profound trance, and sat looking wide-eyed at the author, still blushing.

“I see that you want therapy and that you did as you were instructed.”

Blushing more deeply she nodded her head perseveratively.

“Now stand up in the same way as you did yesterday. Thank you! Now listen to me well, carefully, thoughtfully. Yesterday, quite drastically, in a fashion which you could not avoid understanding and which precluded any possibility of suppression or repression, I asked you to become fully aware of the badge of femininity which you wear, a badge of femininity which you should rightly treasure in all ways.

“But that is not all of which you are to become aware. Tonight, even as last night, in the same sequence of events as I described yesterday, find yourself unexpectedly in the nude in front of the mirror, then suddenly recall all the instructions I have already given you here in the office and which I will give you today.

“Tonight, as you stand in the nude in front of the mirror, look at your badge of femininity, be pleased with it, even blush, and then suddenly, as if it were for the first time that you saw them, look well at the two emblems of womanhood you wear on your chest.

“Examine them carefully, both visually and tactually, thinking over carefully all the things that you know I could tell you to think—all of the things I could tell you to think over. Is it necessary for me to elaborate?”

She slowly shook her head.

“Will you do it even more elaborately than you think I would order you to do the task?”

Ann began blushing in waves as she tried to turn her head aside, and then, yielding, she nodded her head affirmatively.

She was then instructed to return the next day and to appear in the same dress and outwardly unchanged. Next, she was told to sit down, to arouse from hypnosis with a complete amnesia for everything until the crucial moment before the mirror that night.

As she aroused from the trance, she was told, “That’s all for today.” Her face expressed bewilderment, she looked at her watch in a most puzzled fashion, but she departed without saying anything.

She appeared on time the next day, blushing deeply as she entered the office. Without any hesitation she promptly closed the door, sat down in the chair, and immediately developed a profound somnambulistic trance; her blushes disappeared.

She was immediately asked, “Do you want to say something?”

She nodded her head.

“All right, say it now to your full satisfaction.”

Promptly she stated, “I did all you said, I did it better, I think, than you could have asked.” Then with many blushes she asked, “Do I have to tell you?”

“No, Ann, the fact that you have obeyed instructions fully, even better than I could expect, and since your question implies your willingness to cooperate in therapy by relating things you reasonably can expect me not to know, your progress is entirely satisfactory.”

Ann ceased blushing and waited expectantly.

“Did you remember everything both times upon awakening, yet handle your awarenesses well throughout the following day?”

Ann nodded affirmatively.

“Now stand up as before, beside your chair. Today’s task is much harder, much, much harder, much more troublesome, much more painful. Upon leaving here you will notify your office that you will not be there the rest of the day. You will leave here with an amnesia for what I am about to say to you, but still fully consciously aware of the learnings you have acquired the past two nights.

“Listen well! You have heard how many a mother gets her small child neat and clean and declares that it seems to her that in only a few moments’ time he becomes unbelievably untidy. Now listen, Ann! This is the third day you have been in the office. It is not the first time you have worn a dress three days in succession. I merely ensured no accidental change of dress. Now listen carefully, storing every word in your unconscious mind for sudden, full conscious memory when you find yourself in front of your mirror promptly upon returning to your apartment after leaving this office. Do you understand?”

Ann nodded her head slowly, apparently bewildered by the author’s rather sharp tone of voice.

“Ann, your dress looks horrible. It’s saggy and baggy and it fits you like any old potato sack, and it is wrinkled and perspiration-stained, and you don’t have a decent-fitting, decent-looking dress in your entire wardrobe. Every one is an insult to the eye. No taste, wrong colors, wrong everything, and yet you wear them to the office, on the street. When you find yourself in front of the mirror today, with full conscious memory of all that I have said and will say in this office today, examine each and every dress you have, model it, note the ill fit, the sweat stains, spots, rips, loose buttons on blouses—see how competently you dress to be an eyesore.

“And worse, Ann. Look at your hair. Never have I seen it properly combed in the six months I have known you. Always at least a couple of snarls, and that parting of your hair, how do you make it so outrageously crooked? Take a hand mirror and use it to help you to see in the large mirror. A woman’s hair is ‘her crowning glory’ or, in your case, Ann, your crowning disgrace.

“More yet! Have you a personal prejudice about washing your ears and behind them? Don’t answer, but look in the mirror and get an answer then! And your neck! You take a shower or a tub bath, but how do you forget to wash your neck? It must be an art, an undesirable art. Who would want to neck with a dirty-necked girl, a dirty-necked girl like you?

Shudder about that a bit as you look in the mirror. If you want feminine corroboration of all I’m saying, get Agnes to let loose some of her suppressed feelings. You will like them less than what I am saying to you. “How often do your fingernails go into mourning with that line of black dirt under your poorly trimmed fingernails? Do you think it is pleasing to hold hands with a girl whose fingernails are in mourning? Don’t answer.
The questions are rhetorical. For six months I have known you with mussy hair, dirty ears and neck, displeasing, disgusting fingernails, and ill-fitting, untidy dresses, wrinkled stockings—take a look at those, too, tonight. What a slob you are outwardly!”

“You have $700 in the bank. You can borrow money. Go downtown to Department Store X. Seek out Miss Y. I know her; Agnes knows her; I’ve spoken to her sufficiently about your needs. Tell her that you want her to teach you that vast amount of learning you lack but which every woman should have as second nature. Miss Y will be reasonable; accept instruction fully, buy everything you need, get some pretty dresses that fit you, some deodorants and antiperspirants, learn to comb your hair—say a happy goodbye to your $700 and what more you borrow. Arrange for time off work—this I know is possible. There is more I could say, but it really isn’t necessary to elaborate.

There is just one question that intrigues me, but do not answer. It is, where did you get the good sense to go to the dentist to keep your teeth in such good shape, or do you just naturally have such beautiful teeth? Well, use them to sink into the task before you.

“Now you are to leave here with a total amnesia for all that has occurred today in this office. For any reason that comes to mind, notify the office of your absence for the rest of the day. Go to your apartment. Look around happily. It is neat and tidy. Agnes has told

me so. Feel pleased with it. Then step to the mirror and let the 'horror show' begin, and stay to the bitter end and then realize what happiness can be yours.

"A closing remark to you is this: awaken and leave promptly upon grasping the meaning of what next I say. Let me see no more of you until you keep your next appointment as a 'vision of delight.' Now get out of here and close the door from the other side."

She left hurriedly in puzzled bewilderment.

A month passed, and late one afternoon Ann entered the office blushing furiously, smiling happily but embarrassedly, most beautifully gowned. She explained that she was going to a very "special" dinner and dance with a very "special boy friend" and that she would tell the author all about it later, as indeed she did, and she added with much self-consciousness that she hoped she was a "vision of delight."

Within a year Ann was engaged to a physician; she married him shortly thereafter and moved to another part of the country. Occasional news was received about her. At the age of 45 Ann was encountered unexpectedly while she and her family were on a vacation trip. She was the mother of four children; she appeared to be not over 40 years of age, and she was exceedingly happy. Her husband had achieved marked recognition in his specialty, and the entire family was obviously happy and well-adjusted. One careful comment was made by Ann to the effect that, bit by bit, as her daughter grew old enough to understand each item, she intended to teach the child progressively "how to be a vision of delight."

Correcting an Inferiority Complex

Milton H. Erickson

Unpublished manuscript, 1937-1938

A 29-year-old man, employed as a clerk, sought therapy in an ambivalent manner. He explained that, while he wanted therapy, he did not amount to enough to warrant anybody wasting time on him. He had sought therapy from other psychiatrists but had always discontinued because the amount of time that seemed indicated for results was so greatly out of proportion to his worth as a person. He always felt the time spent on him could be better spent on less inferior patients. He had come to the writer in the hope that hypnosis would be used and that his therapy could be expedited without depriving more deserving patients of needed time with the writer.

The suggestion was offered that he probably wished limited therapy that would meet his minimal needs. He agreed with as much enthusiasm as he could muster. He also agreed reluctantly to the idea that preliminary interviews would be spent in securing a necessary factual history, but was somewhat reassured by the statement that he could abbreviate the time by giving freely whatever information the writer wished.

His history can be summarized by first giving the recurrent theme of it and listing illustrative items. “I have never done anything very good, no matter what. I’m completely inferior in everything.” He was the only child of shiftless, ne’er-do-well parents. He had failed to attend the eighth grade graduation ceremonies and felt that he had not really graduated. High school required four and a half years because of time spent in changing schools. Even so, he failed to graduate because he lacked one credit. He was always a hanger-on at social activities in school, and his diffidence and lack of self-confidence precluded any active participation. In high school, despite his excellent physique, he succeeded only in being waterboy for a brief time. He was, in his own words, “a wash-out as a waterboy.” In essence, he was one of those “nice fellows” for whom the general tendency of people is to feel contemptuous pity.

His parents died when he was nearly 18. His first employment had been scattered odd jobs at manual labor. Finally, he secured employment washing cars in a large garage and graduated to the position of handyman and errand boy for everything. This led to his placement in the automobile parts department, where he actually manifested good ability. However, his willingness to work hard for a minimal salary earned him only job security and general disrespect.

On inquiring into minute details of what he could do, numerous, consistent items were discovered. A few of these may be listed:

1. He could not knot his tie neatly, nor could he tie his shoestrings neatly.

2. He was invariably five minutes late coming to work and about 20 minutes late in quitting.
3. Time after time he ruined social engagements arranged on a joint basis for him by associates by making some inept remark, such as telling his girl companion, "He [the other man] always gets the prettiest girl."
4. A final item, which he had mentioned repeatedly in giving his history, was his handwriting. It was practically illegible, and his records at work were a constant source of embarrassment, even though they constituted an insurance against his discharge.
5. One other and highly important theme in his story, reiterated again and again, was "If I could only do one thing good, just one thing, I'd have some pride in myself. Can't you learn me just one thing good?"

TRANCE INDUCTION UTILIZING THE PATIENT'S INFERIORITY COMPLEX

When he had completed his story, he was told that hypnotherapy would be employed. To accomplish this, it was explained that he would be used as a demonstration subject for the writer's medical students and that the therapy would be an incidental part of the instruction of the medical students. This type of cavalier offer to help him utilized his need for inferiority even in the therapeutic situation and actually pleased him. His general pattern of submissiveness aided greatly in inducing a deep trance without difficulty. He learned to manifest readily all the general hypnotic phenomena.

Extensive use was made of posthypnotic suggestions to create situations in which his general inept behavior was brought into sharp contrast with the competent behavior of the medical students. In this way an attitude of dependence upon and security in relation to the writer as a completely tolerant, forgiving protector was established to satisfy his neurotic needs.

HYPNOTIC ROLE-PLAYING FACILITATING OBJECTIVE SELF-PERCEPTION

After about 12 hours of this sort of activity, intermingled with instructional work with the medical students, he was deeply hypnotized and depersonalized. He was then induced to assume the identity of that medical student with whom the writer felt he could most easily identify. This accomplished, the selected medical student, who was an amateur actor, was hypnotized deeply and instructed to assume the patient's identity.

There followed a repetition of various of the procedures previously employed to create special situations with the pseudo-patient duplicating the patient's previous inept behavior. During this the patient, in his identity as a student, participated in the discussion of the induced behavior portraying himself. Thus he was enabled to see himself in an objective, detached fashion and, from unrecognized inner knowledge, to appreciate exactly what was occurring.

When it seemed that there had been sufficient demonstration of his ineptness, one final item not previously employed was utilized. This was a systematic calling upon various but not all of the medical students, one by one, to write and sign the statement, "This is a beautiful day in June." In each case the students were urged to write clearly and legibly. Each written production was then critically examined by the entire group, except the pseudo-patient. Among those not called upon to write was the actual patient.

Next the pseudo-patient was asked to write the same sentence. A horribly illegible scrawl with an indecipherable name was produced. (This student had previously been shown the patient's handwriting and had been asked to study it.) The pseudo-patient was urged again and again to write more legibly, but each production remained illegible.

After discussion of this with the group, the writer explained at length that the "patient" could be taught to write easily and legibly by the utilization of a special technique. Thereupon the medical student, in his role as the patient, was regressed to an earlier childhood level and asked to write simple statements. He did this in a typical childish handwriting, but legibly so. After securing samples of his handwriting at various age levels, he was reoriented to the original trance state. Again he produced illegible scrawls.

SERIAL POSTHYPNOTIC SUGGESTIONS AND AUTOMATIC WRITING

He was then given a series of posthypnotic instructions to awaken and, at a specified cue, to write clearly and legibly, "It is not raining tonight" and to sign it with the names of several classmates. This writing, it was explained, would be done automatically, and he would not know who wrote it since it would be written with such legibility. Also, at a second cue he would write the same sentence again with great care and still not know that he had written it. In fact, he would vigorously deny having written either production, insisting that he could not write that legibly.

The pseudo-patient obeyed instructions in full, and his illegible and legible productions were passed around the group for criticism and discussion, while he vigorously claimed that he had not written them, a claim rendered recognizably valid by his posthypnotic amnesia.

Following this, the patient, still in a trance, was reoriented hypnotically and his identity restored. He was immediately regressed to various childhood levels at each of which he was asked to write clearly and legibly the sentence, "This is a beautiful day in June," signing his name each time and recording his age and the date. At the 14-year level a prolonged series of suggestions was given him to the effect that when he was a grown man, he would be called upon to do the same thing, and a promise was elicited that he would. He was then reoriented to the current situation with an amnesia for trance events, though still in a deep trance.

With great emphasis and care he was given a long series of posthypnotic suggestions to the effect that upon certain specified cues he would, after awakening, write automatically

the sentence, “It is a beautiful day in June,” and sign it with his name. He would not know he was doing this, and he would vigorously deny having written it. Furthermore, while writing it, he would be engaged in discussing with the medical students some topic that would be raised. (The medical students were posted to have in readiness such topics as the city’s population 10 years ago, the street location of some building, etc.)

Additionally, the posthypnotic cue would be repeated a number of times, and each time the writer would raise some question as, “I wonder if the same writing will appear on the next sheet,” or, “I expect the next signature will have the full middle name, instead of the initial.” Each such question was to be responded to by the execution of the implied suggestion.

When it seemed reasonably certain that he understood, he was awakened. After a few casual remarks, at a glance from the writer, one of the students began discussing a topic. The writer drummed briefly on his desk with his fingers. The patient abstractedly picked up a pencil and, while attending to the discussion directed at him, wrote the sentence and signed it with his first and last names and middle initial, all in legible fashion.

This sheet was quietly removed, a new topic raised, the cue given, and the question voiced by wondering if the sentence would be written. The patient responded exactly as he had been instructed. This time his attention was called to the completed writing, and he was asked if he had done it.

There followed his denials and the animated assertions of the students that he had written it. The patient “proved” his contention by copying the same sentence in his usual illegible script underneath his automatic writing. His “proof” was accepted with a show of much reluctance, and the writer took advantage of this development by asking him to scrutinize that page most carefully, to memorize its appearance thoroughly, and to be prepared to recognize it when shown it again. The sheet was then quietly put out of sight along with the first.

He was asked to count the sheets of paper on the desk and to examine them carefully, one by one, to determine if there were any writing on them. When he affirmed that there was none, he was engaged in a new topic of conversation, the cue was given as the writer “wondered” if his name would appear on the uppermost sheet. Automatically his hand wrote legibly without his knowledge.

Again the procedure was repeated, this time the writer wondering if the top sheet would be placed underneath the other sheets and if his full name would be written on the next. Absentmindedly he straightened out the sheets, slipping the top one underneath and writing his full name on the exposed sheet.

The procedure continued with the items listed below written, one by one, clearly and legibly. Repeatedly his attention was called to the fact that everybody was fully 10 feet away from him. The repetition of this puzzled him greatly.

Sheet 3: "My birthday is November 9th. I was born in Lodi."
4: "Natalie Williams."
5: "2 3 8 1 9 2 9"
6: "Look on the next sheet for the name of the person writing this sentence."
7: "John Robert Doe."
8: "You don't believe it, do you?"
9: "You will—you really will."
10: "Didn't know you could write well, did you, John R. Doe?"
11" "You are about to find out that you can write well, and you will really know it. You will watch yourself writing and you will see it with your own eyes."

This last sheet was placed at the bottom of the pile. He was then interrupted and asked if any further writing had appeared on the paper since that sentence. He shook his head, remarked that the group was too far away, glanced at the stack of paper, and added that it was ready for writing if anybody wished to do any. He was asked if he still remembered the sheet he had been asked to memorize. He nodded his head, and the writer stepped over and handed it to him. He pointed at the "strange writing" and his own and showed it to each one in the group.

He was asked to be most certain about his statements concerning the writing and to hand it to the writer. While the patient's attitude was distracted for a moment, the first sheet was substituted and he was again asked if he were certain about the writing. As he asserted he was, the first sheet was extended to him for apparently a reinspection. He was tremendously startled to find that "his writing" had disappeared and that the "strange writing" had moved to a different position on the sheet. Further manipulation of the sheets bewildered him still more, until he declared that he did not know what to think since he knew the author was not a magician. He was assured at once that he would soon know what to think, and he would then be right.

Next he was asked to examine the stack of paper in front of him and to see if there was writing on the various sheets. He asserted that he knew there was none, but upon request he started examining them one by one.

The first few sheets were of course blank. When he came to Sheet No. 3, he commented in astonishment, "That's the same as my birthday, and I was born in Lodi. That's funny." At Sheet No. 4 he was even more startled, commenting in amazement that that was his mother's maiden name.

Sheet No. 5 bewildered him completely, and he disclaimed any understanding. However, when asked for his present street address and any other past addresses he remembered, he complied and then suddenly recognized the house number where he had lived in 1929. Immediately he looked at the next sheet, hastily read it, and then uncovered Sheet 7. He read his name aloud to himself, declaring that it was his name, that nobody else there knew his middle name, that it was not his writing, which it could not be. He reexamined

the other sheets, including the first two. This discovery of the first sheet and the second as two different written productions confused him still further.

Upon reading Sheet 8 he was too dumbfounded to speak, except to say, "I can't; I didn't." Then, after looking hesitantly around, almost furtively, he looked at Sheet 9, shook his head uncertainly, and slowly lifted the sheet to see No. 10. This he read aloud to himself in a puzzled, bewildered fashion and finally asked, "What is going on? What is happening?"

The reply was offered, "You are learning something most important. Why not look at the next sheet?" Obediently he uncovered the next sheet, read it carefully, and turned to the writer as if waiting.

Immediately, a posthypnotic cue previously employed to induce a trance was given. He developed a deep trance at once and was instructed, "You know unconsciously the whole truth about the writing unconsciously, and you are now ready to know it consciously. You can write well, you can take pride in doing something well, and more than that, you know, really know, that you can do many things well. Only one thing remains to be done before you can use all this understanding to change your ways of doing many things. That one thing that needs to be done will be done shortly.

VISUAL HALLUCINATIONS TO FACILITATE OBJECTIVE SELF-PERCEPTION

"I want you to look in that crystal ball right there and see yourself writing in the unhappy, miserable fashion you have for so long. See yourself plainly. Now that that is done, see a second crystal ball alongside that one. In it you now see yourself writing legibly, and as you watch, a tremendous flood of joy and happiness and confidence and pride will well up in you, ready to become shown as soon as you awaken and watch your handwriting, 'This is a beautiful day in June. Signed: John R. Doe.' You will watch your hand write this and then write it a second time. Then you will put the sheet away and turn to me and tell me from the bottom of your heart that you can write well and you will show me by writing whatever you wish. And then all the happiness in the world will well up in you, just like in a happy little boy, a growing boy, just like in a teenager who has won first place, like a young man that has succeeded in his first big job. This joy you will really share with everybody, and we will enjoy your happiness because it means everything in so many ways to you. Now awaken and watch first how your hand writes."

Instructions were followed fully, and the writing he did of his own determining was, "I can really write—1 can really do a lot of things I am going to do. John R. Doe."

Upon reading it through, he leaped to his feet and, at first childishly, then boyishly, then youthfully, demanded over and over that each of the medical students, as well as the writer, read his writing, comment on it favorably, and watch him do further writing. About 15 minutes was spent in this emotional display. Then suddenly he gathered up his papers, handed them to the writer, and said "Thank you." Turning to the students he said,

“Excuse me a moment, gentlemen,” sat down, undid his knotted shoestrings, and tied them in neat bows.

Straightening up, he addressed them, “I want to thank you gentlemen, too. If you ever need any automobile parts, I’ll give you the best service in the world.” After shaking hands all around, he took his departure, but he was observed entering the men’s room. When he came out, his tie was neatly knotted.

He was seen two weeks later. He reported that he had been working overtime, extensively recopying for his employer all the past records of parts received and sold, so that his employer would have decent records. A month later he had received a promotion and a marked increase in salary. He had developed his social life and had joined an amateur theatrical group and was at the present rehearsing regularly for one of the leading roles. He had also been having social engagements with a young woman of his age.

A year later he was decidedly happy in a minor executive position in a large automobile-accessory firm and was considering marriage. Several years later word was received indirectly that he was happily married and still employed by the same firm.

The Hypnotherapy of Two Psychosomatic Dental Problems

Milton H. Erickson

Reprinted with permission from the *Journal of the American Society of Psychosomatic Dentistry and Medicine*, 1955, 1, 6-10.

In the practice of psychiatry one frequently encounters patients whose problems center around some physical attribute with which they are dissatisfied. Too often they seek help from those trained to deal with such physical aspects of the body, but who have not had the training or the experience necessary to recognize that the primary consideration is the patient's personality reaction, not the patient's physical condition.

Consequently, efforts to alter the physical state, regardless of the technical skill employed and the excellence of the results obtained, are not appreciated, since the patient's hopeful expectations are not limited to the actual possibilities of the physical realities. Particularly is this true in the fields of dentistry and plastic surgery, where sometimes the most skillful work may fail to meet the emotional demands of the patient.

To illustrate this general type of psychosomatic problem in the field of dentistry, two case histories are to be cited below. In each instance the patient seized upon a dental anomaly as the explanation of a definite personality maladjustment. For each, the problem of therapy was not a correction of the dental problem but a recognition of emotional needs.

Several examples of the first type of patient have been seen. Among them was one who underwent an extraction and a fitting with a denture. Her maladjustment continued, increased by her permanent dissatisfaction with the dental work. Another had centered all her life around her neurotic reactions, scorning any type of treatment. A third had been comfortingly told, when she sought dental intervention, that she should take pride in being unique, and so well had the dentist done this that she had adjusted satisfactorily.

Two examples of the second type have been seen. Both of those bitterly resented the dental correction that had been made, since they had been left with their primary personality problem unsolved.

Neither of the writer's patients reported here had sought correction of their dental anomalies nor had their dentists suggested any need for correction.

While the cases to be cited represent primarily problems best handled by a psychiatrist, there is a need for those in allied fields to be aware of the nature and possible seriousness of seemingly minor psychosomatic reactions and of the opportunities of dealing more adequately with them.

PATIENT A

A high school girl sought psychiatric help because she was failing her Second-year work and because she had barely succeeded in meeting the first year's requirements. Her reason for coming to the writer was that she knew he was a hypnotist and because she had been much impressed by an extracurricular lecture he had given at the high school. As she entered the office, she remarked that she would probably be hypnotized by a single glance from the writer and that she probably would not even know she was in a trance. No effort was made to disillusion her.

She had come without her parents' knowledge because she felt that they would not understand her problem. Nor could she go to anybody else she knew because they would only minimize her problem and reassure her "falsely."

Her complaint was that she was an "absolute freak" in appearance because she had only one double-sized upper incisor tooth. This had not troubled her until the development of physiological maturity and a concurrent change in residence, making necessary admission to a high school where she knew nobody.

Her reaction to her personal and school situation had been one of withdrawal, seclusiveness, and the development of much wishful thinking in which her teeth were "normal." She found herself extremely self-conscious, was unwilling to eat in the school cafeteria, and avoided smiling or laughing at every cost: her enunciation of words was faulty because of her voluntary rigidity of her upper lip. However, her attitude in the office was one of ease, which she explained was because she was probably hypnotized.

During the interview it was noted that she relied almost exclusively on slang and "jive talk." Even in making serious remarks, she couched them in extravagances of slang.

For the next two interviews she was encouraged to display her actually extensive knowledge of, and fluency in, past and current slang, and she was delighted to display her ability. Additionally, she was an excellent mimic and had a remarkable command of accents, which she was most ready to display. Accordingly she was asked to demonstrate at length the "choppy" speech of the British and the "bitten off" enunciation of the Scotch. Also, she had an extensive knowledge of popular songs, past and present, comic strips, nursery tales, and light literature of all sorts.

The next interview was devoted to an extensive discussion of the picturesqueness of slang. This conversation unnoticeably and deviously led into a discussion of expressions, such as L'il Abner's "chompin' gum," "what big teeth you have, Grandmother," "Ol' Dan Tucker, who died with a toothache in his heel," "putting the bite on Daddy for more pocket money," "sinking a fang in a banana split," and various other expressions or phrases containing references to teeth or dental activity.

She was interested and pleased but also amused by the writer's effort to talk in "hep" style. She contributed gladly and readily to the discussion by calling upon her extensive

knowledge of references to teeth in popular songs, nursery tales, comics, and slang, without seeming to note the personal implications.

For the next interview she promised to "rattle the ivory" with every reference she could "dig up, from China Choppers to the Elks' Club." The next session was fascinating. In response to a request, in rapid-fire fashion, alternating from the British to the Scottish pattern of speech, utilizing slang to do so, she proceeded to give, from song, stories, ditties, doggerel, comics, fables, and slang old and new, innumerable references to teeth.

When she finally began to slow down, the remark was made, "When you put the bite on a job, you really sink your fang into it, but then, you've got the really hep accessory for that. Use your choppers now to chop off a bit more of the British and your fang to bite off a bit more Scotch."

She paused abruptly, apparently suddenly realizing both the personal implications and the fact that teeth could be an interesting, amusing, and pleasingly fascinating subject. Immediately, since she also liked puns immensely, she was reminded of the comic, "That's my Pop," and told to go home, look into the mirror, smile broadly, and then say, "That's my maw." If she did not understand, she was then to consult a dictionary. At the next interview she was full of smiles and laughter, greeting the writer with a wide grin and saying, "Yes sir, that's my maw."

Asked what she had been doing since the last interview, she replied that she had been having a good time "chewing international fat" (talking with various accents), thereby bewildering her teachers and entertaining her schoolmates. Asked if she felt that she were a freak, she stated that she did not but that her instructors surely did when she "chewed the frog, the sauerkraut, or the cornpone" (French, German, and Southern accents).

Subsequently, one of her high school teachers, in discussing pedagogical problems with the author, commented on a remarkable transformation of one of his students. He had first noted her as a shy, withdrawn, and inept student, one whose speech was faulty and whose recitations were unsatisfactory. Then one day she had given a faultless recitation with a strong British accent, repeating the performance on another day with a Scottish accent. Subsequently, he had heard her chattering to a group in the corridor with a Norwegian accent. He regarded her as a decidedly brilliant student, though rather inexplicable in her adolescent behavior.

Still later another instructor, in discussing his Ph.D. thesis on aspects of high school behavior, cited the instance of this same girl's remarkable transformation and her amazing linguistic abilities, which had rendered her a popular and well-adjusted, competent student.

PATIENT B

A 21-year-old girl, employed as a secretary for a construction firm, sought therapy because "I'm too inferior to live, I think. I've got no friends, I stay by myself. I'm too

homely to get married. I want a husband, a home, and children, but I haven't a chance. There's nothing for me but work and being an old maid, but I thought I'd see a psychiatrist before I committed suicide. I'm going to try you for three months' time and then, if things aren't straightened out, that's the end."

She was utterly final in this attitude, and consented to only two therapeutic hours a week for three months. She paid in advance and stipulated that she be discharged at the close of the thirteenth interview. (She checked the calendar and counted the number of possible interviews.)

She was not communicative about her past history. Her parents, neither of whom had wanted her, had been unhappy as long as she could remember. They were killed in an automobile accident shortly after her graduation from high school. Since then she had lived in rooming-houses and had worked at various stenographic and secretarial jobs. She changed jobs frequently because of self-dissatisfaction.

Concerning herself and her feelings of inferiority, she listed them bitterly as follows:

1. There is an unsightly wide space between my two upper front teeth. It's horrible and I don't dare to smile. (With difficulty she was persuaded to show this. The spacing was about an eighth of an inch.)
2. I can't talk plain. (From holding her upper lip stiff.)
3. My hair is black, coarse, straight, and too long.
4. My breasts are too small, and my hips are too small.
5. My ankles are too thick.
6. My nose is hooked. (Actually very slightly.)
7. I'm Jewish.
8. I'm an unwanted child, always have been, always will be.

In explaining this list of defects, all emphasis was placed upon the spacing of her upper incisors. To her that was the causation of all her difficulties. She felt that she could adjust to the "other things," but this "horrible spacing" rendered impossible for her any hope of adjustment.

After her unhappy description of herself, she sobbed and then endeavored to leave, declaring, "Keep the money, I won't need it where I'm going." However, she was persuaded to keep to her original plan of three months' therapy.

Contrary to her description of herself, she was definitely a pretty girl, well-proportioned, and decidedly attractive. She was graceful in her movements and had good posture, except for her downcast head.

Her general appearance, however, was most unattractive. Her hair was straggly, snarled, and uneven in length. (She cut it herself.) The part was crooked and careless. Her blouse lacked a button, there was a small rip in the skirt, the color combination of the blouse and the skirt was wrong, her slip showed on one side, her shoes were scuffed, and her shoestrings were tied in unsightly knots. She wore no makeup, and while her fingernails

were well-shaped, remnants of fingernail polish were on only one hand. (She had started to apply fingernail polish a few days previously but was too discouraged to complete the task or to remove the evidence of her attempt.)

During the next four sessions she was sullen and uncooperative, insisting that the writer earn his fee by doing all the talking.

However, it was learned that she was intensely attracted to a young man two years older than she who also worked at her place of employment. She usually arranged to observe him when he went to the drinking fountain down the corridor, but she ignored him and never spoke to him, although he had made overtures. Inquiry disclosed that the fountain trips were rather numerous. She made it a point to go whenever he did, and apparently he behaved similarly. This had been taking place for the last two months.

She proved to be a rather poor hypnotic subject and only a light trance could be induced. Hence, all these and subsequent interviews were conducted in the light trance.

The next four sessions were primarily devoted to building up the general idea that, by a certain date, she was to acquire a completely new, but quiet and modest outfit of clothes and to have her hair dressed at the beauty shop. Then, at a date set by the writer, she was to go to work in her new clothes. (During this period of time she continued to wear the same clothes she had worn at the first interview). The rationalization was

offered her that since she was not optimistic about the future, she might as well have "one last fling."

The next two sessions were spent on the subject of her "parted teeth." She was given the assignment of filling her mouth with water and squirting it out between her teeth until she acquired a practiced aim and distance. She regarded this assignment as silly and ridiculous, but conscientiously practiced each evening because "it doesn't really matter what I do."

The two following sessions were devoted, first indirectly and then more and more directly, to the idea that she would make use of her newly acquired skill of squirting water as a practical joke at the expense of the desirable young man.

At first she rejected the idea, then accepted it as a somewhat amusing but crude fantasy, and finally she accepted it as a possibility to be definitely executed.

The final plan evolved was that the next Monday, dressed in her new outfit, her nails polished and her hair having been dressed the previous Saturday at the beauty shop, she would await a favorable opportunity to precede the young man to the drinking fountain. There she would await his approach, fill her mouth full of water, and spray him. Then she was to giggle, start to run toward him, turn suddenly and "run like hell down the corridor."

As was learned later, she carried out the suggestions fully. Late in the afternoon she had seized an opportunity to execute the plan. His look of consternation and his startled exclamation of, "You damn little bitch," evoked her laughter at him. When she ran, he, quite naturally, pursued her and caught her at the end of the corridor. Upon seizing her he declared, "For that kind of a trick, you're going to get a good kissing" and suited his action to his words.

The next day, rather timid and embarrassed, she warily went to the fountain for a drink. As she bent over the fountain, she found herself being sprayed with a water pistol by the young man concealed behind a telephone booth. She immediately filled her mouth with water and charged him, only to turn and run wildly as he met her charge head on. Again she was caught and kissed.

The patient failed to keep her next two appointments, and then came in at the next regular time, thoroughly well groomed in appearance.

She gave the foregoing account, and stated that the second episode had resulted in a dinner invitation. This had been repeated two days later. Now she was considering the acceptance of another invitation for dinner and the theater.

She explained further that the outcome of the silly prank suggested to her by the writer had caused her to spend many thoughtful hours "taking inventory of myself." As a result she had one request to make of the writer—namely, would he coldly, judiciously, and honestly appraise her to detail? When this was done, she would terminate therapy. The smile with which she made this statement was most reassuring.

Accordingly, her request was met by discussing:

1. Her original woebegone, desperate emotional attitude.
2. Her unkempt, frumpish appearance.
3. Her unwarranted derogation of her physical self.
4. Her misconception of a dental asset as a liability.
5. Her sincerity and cooperation in therapy, however bizarre had seemed the ideas presented.
6. The readiness with which she had assumed self-responsibility in reacting to pleasurable life situations.
7. The obvious fact that she now recognized her own personal values.
8. Her need to review her objectives in life as stated in the original interviews.
9. Her personal attractiveness, not as seen only by herself but as appreciated from the masculine point of view.

She listened attentively and, at the close of the interview, thanked the writer graciously and took her departure.

Several months later a marked copy of the local newspaper was received in the mail containing an announcement of her engagement. About six months later an announcement of her marriage to the young man was received. Then, 15 months later, a letter was received containing a snapshot of her home, the announcement of her son's

birth, and a newspaper clipping announcing her husband's promotion to junior member of the construction firm. Since then no direct word has been received, but she has referred to the writer several patients who speak glowingly of her.

DISCUSSION

Although both of these patients emphasized their dental complaint as the fundamental consideration in their maladjustment, the case histories have been reported without distortion. Instead, an effort has been made to present the general situation of which the dental aspect constituted merely the one item which had been seized upon to represent completely a total problem.

Therapy for both was predicated upon the assumption that there is a strong normal tendency for the personality to adjust if given an opportunity. The simple fact that both patients had centralized their complaints upon one single item of a psychosomatic character, which was alterable if necessary, suggested that prolonged, extensive probing into the experiential life of the patients and elaborate reeducation were not necessarily indicated.

The therapeutic results obtained indicate that an uncomplicated psychotherapeutic approach may be most effective in a circumscribed psychosomatic reaction. Had this method failed with these two patients, there would still have remained the possibility of a more elaborate psychotherapeutic procedure.

The Identification of a Secure Reality

Milton H. Erickson

Reprinted with permission from *Family Process*, September, 1962, 1, 294-303,

Reality, security, and the definition of boundaries and limitations constitute important considerations in the growth of understanding in childhood. To an eight-year-old child the question of what constitutes power and strength and reality and security can be a serious matter. When one is small, weak, and intelligent, living in an undefined world of intellectual and emotional fluctuations, one seeks to learn what is really strong, secure, and safe.

A 27-year-old mother began to encounter serious difficulty with her Eight-year-old son, who was becoming progressively defiant and seemed to find a new way to defy her each day. The mother had divorced her husband two years previously for adequate reasons recognized by all concerned. In addition to her son she had two daughters, aged nine and six. After some months of occasional dating with men in the hope of marriage, she found her son had become rebellious and an unexpected problem. The older daughter had joined him briefly in this rebelliousness. The mother was able to correct the daughter by her customary measures of discipline through anger, shouting, scolding, threatening, and then an angry spanking followed by an intelligent, reasonable, objective discussion with the child. In the past this had always been effective with the children. However, her son Joe refused to respond to her usual measures, even when she added repeated spankings, deprivations, tears, and the enlistment of her family's assistance. Joe merely stated, quite happily and cheerfully, that he planned to do whatever he pleased and nothing, just nothing, could stop him.

The son's misbehavior spread to the school and to the neighborhood, and literally nothing was safe from his depredations. School property was destroyed, teachers defied, schoolmates assaulted; neighbor's windows were broken and their flower beds destroyed. The neighbors and teachers, endeavoring to take a hand in the matter, succeeded in intimidating the child, but nothing more. Finally the boy began destroying things of value in the home, especially after the mother was asleep at night, and then he would infuriate her by boldfacedly denying guilt the next morning.

This final mischief led the mother to bring the boy in for treatment. As the mother told her story, Joe listened with a broad, triumphant smile. When she had finished, he boastfully declared that the author could not do anything to stop him and he was going to go right on doing as he pleased. The author assured him, gravely and earnestly, that it was unnecessary for him to do anything to change the boy's behavior because he was a good, big, strong boy and very smart, and he would have to change his behavior all by himself. The boy was assured that his mother would do just enough to give him a chance to change his behavior "all by himself." Joe received this statement in an incredulous

sneering manner. Then he was sent out of the office with the statement that his mother would be told some simple little things that she could do so that he himself could change his behavior. He was also earnestly challenged in a most kindly fashion to try to figure out what those simple little things might be. This served to puzzle him into quiet reflective behavior while he awaited his mother.

Alone with the mother, the author discussed a child's demand for a world in which he could be certain that there was someone stronger and more powerful than he. To date her son had demonstrated with increasing desperation that the world was so insecure that the only strong person in it was himself, a little eight-year-old boy. Then the mother was given painstakingly clear instructions for her activities over the next two days.

As they left the office, the boy challengingly asked if the author had recommended spankings. He was assured that no measure would be taken except to give him full opportunity to change his own behavior; no one else would change it. This reply perplexed him, and on the way home his mother administered severe corporal punishment to compel him to let her drive the automobile safely. This misconduct had been anticipated; the mother had been advised to deal with it summarily and without argument. The evening was spent in the usual fashion by letting the boy watch television as he wished.

The following morning the grandparents arrived and picked up the two daughters. Joe, who had plans to go swimming, demanded his breakfast. He was most puzzled when he observed his mother carry into the living room some wrapped sandwiches, fruit, one Thermos bottle of fruit juice and one of coffee, and some towels. She put all these items securely on a heavy couch with the telephone and some books. Joe demanded that she prepare his breakfast without delay, threatening physical destruction of the first thing he could lay his hands on if she did not hurry. His mother merely smiled at him, seized him, threw him quickly to the floor on his stomach, and sat her full weight upon him. When he yelled at her to get off, she replied mildly that she had already eaten breakfast and she had nothing to do except to try to think about ways to change his behavior. However, she pointed out that she was certain she did not know any way; therefore it would all be up to him.

The boy struggled furiously against the odds of his mother's weight, strength, and watchful dexterity. He yelled, screamed, shouted profanity and obscenities, sobbed, and finally promised piteously always to be a good boy. His mother answered that the promise did not mean anything because she had not yet figured out how to change his behavior. This evoked another fit of rage from him, which finally ceased, followed by his urgent plea to go to the bathroom. His mother explained gently that she had not finished her thinking; she offered him a towel to mop up so he would not get too wet. This elicited another wild bit of struggling, which soon exhausted him. His mother took advantage of the quiet to make a telephone call to her mother. While Joe listened, she explained casually that she had not yet reached any conclusion in her thinking and she really believed that any change in behavior would have to come from Joe. Her son greeted this remark with as loud a scream as he could muster. His mother commented into the

telephone that Joe was too busy screaming to think about changing his behavior, and she put the mouthpiece down to Joe's mouth so that he could scream into it.

Joe lapsed into sullen silence, broken by sudden surges of violent effort, screams, demands, and sobbing interrupted by piteous pleas. To all of this his mother gave the same mild, pat answers. As time passed, the mother poured herself coffee, fruit juice, ate sandwiches, and read a book. Shortly before noon the boy politely told her he really did need to go to the bathroom. She confessed a similar need. She explained that it would be possible if he would agree to return, resume his position on the floor, and let her sit down comfortably upon him. After some tears, he consented. He fulfilled his promise, but almost immediately launched into renewed violent activity to dislodge her. Each near success led to further effort, which exhausted him still more. While he rested, she ate fruit and drank coffee, made a casual telephone call, and read a book.

After over five hours Joe surrendered by stating simply and abjectly that he would do anything and everything she told him to do. His mother replied just as simply and earnestly that her thinking had been in vain; she just did not know what to tell him to do. He burst into tears at this, but shortly, sobbing, he told her he knew what to do. She replied mildly that she was very glad of this but she did not think he had had enough time to think long enough about it. Perhaps another hour or so of thinking might help.

Joe silently awaited the passing of an hour while his mother sat reading quietly. When over an hour had passed, she commented on the time but expressed her wish to finish the chapter. Joe sighed shudderingly and sobbed softly to himself while his mother finished her reading.

With the chapter finally finished, the mother got up and so did Joe. He timidly asked for something to eat. His mother explained in laborious detail that it was too late for lunch, that breakfast was always eaten before lunch, and that it was too late to serve breakfast. She suggested instead that he have a drink of ice water and a comfortable rest in bed for the remainder of the afternoon.

Joe fell asleep quickly but awakened to the odors of well-liked foods. His sisters had returned, and he tried to join them at the table for the evening meal. His mother explained—gravely, simply, and in lucid detail—that it was customary first to eat breakfast and then lunch and then dinner. Unfortunately, he had missed his breakfast, therefore he had to miss his lunch. Now he would have to miss his dinner, but fortunately he could begin a new day the next morning. Joe returned to his bedroom and cried himself to sleep. The mother slept lightly that night, but Joe did not arise until she was well along with breakfast preparations.

Joe entered the kitchen with his sisters for breakfast and sat down happily while his mother served his sisters with pancakes and sausages. At Joe's place was a large bowl. His mother explained that she had cooked him an extra—special breakfast of oatmeal, a food not too well liked by him. Tears came to his eyes, but he thanked her for the serving, as was the family custom, and ate voraciously. His mother explained that she had cooked

an extra supply so that he could have a second helping. She also cheerfully expressed the hope that enough would be left over to meet his needs for lunch. Joe ate manfully to prevent that possibility, but his mother had cooked a remarkably large supply.

After breakfast Joe set about cleaning up his room without any instruction. This done, he worked hard picking up the stones he had thrown on the lawn. When he asked his mother if he could call upon the neighbors, she had no idea what this portended but gave permission. From behind the window curtains she watched him while he went next door and rang the bell. When the door opened, he apparently spoke to the neighbor briefly and then went on up the street. As she later learned, just as systematically as he had terrorized the neighborhood, he canvassed it to offer his apologies and to promise that he would come back to make amends as fast as he could. He explained that it would take a considerable period of time for him to undo all the mischief he had done.

Joe returned for lunch, ate buttered, cold, thick sliced oatmeal, helped voluntarily to dry the dishes, and spent the afternoon and evening with his schoolbooks while his sisters watched television. The evening meal was ample but consisted of leftovers, which Joe ate quietly without comment. At bedtime Joe went to bed voluntarily while his sisters awaited their mother's usual insistence.

The next day Joe went to school, where he made his apologies and promises. These were accepted warily. That evening he became involved in a typical childish quarrel with his older sister, who shrieked for her mother. As the mother entered the room, Joe began to tremble visibly. Both children were told to sit down, and the sister was asked to state her case first. When it became his turn to speak, Joe said he agreed with his sister. His mother then explained to Joe that she expected him to be a normal eight-year-old boy and to get into ordinary trouble like all regular eight-year-old boys. Then she pointed out to both of them that their quarrel was lacking in merit and was properly to be abandoned. Both children acquiesced.

GAINING MOTHER'S COOPERATION

The education of Joe's mother to enable her to deal with her son's problem by following out the instructions was a rather difficult task. She was a college graduate, a highly intelligent woman with a background of social and community interests and responsibilities. In the interview she was asked to describe, in as full a way as possible, the damage Joe had done in the school and the community. With this description the damage became painfully enlarged in her mind. (Plants do grow back, broken windowpanes and torn dresses can be replaced, but this comfort was not allowed to be a part of her review.)

Next she was asked to describe Joe "as he used to be"—a reasonably happy, well-behaved, and actually a decidedly brilliant child. She was repeatedly asked to draw these comparisons between his past and present behavior, more briefly each time, but with a greater highlighting of the essential points. Then she was asked to speculate upon the probable future of Joe both "as he used to be" and as was "quite possible" now in the

light of his present behavior. Helpful suggestions were given to aid the mother in drawing sharply contrasting "probable pictures of the future."

After this discussion she was asked to consider in full the possibilities of what she could do over the weekend and the kind of role she ought to assume with Joe. Since she did not know, this placed her completely in a passive position, so the author could offer plans. Her repressed and guilty resentments and hostilities toward her son and his misbehavior were utilized. Every effort was made to redirect them into an anticipation of a satisfying, calculated, deliberate watchfulness in the frustrating of her son's attempts to confirm his sense of insecurity and to prove her ineffectual.

The mother's apparently justified statement that her weight of 150 pounds was much too great to permit putting it fully on the body of an eight-year-old child was a major factor in winning the mother's full cooperation. At first this argument was carefully evaded. The mother was helped systematically to marshal all of her objections to the author's proposed plans behind this apparently indisputable argument that her weight was too great to be endured by a child. As she became more entrenched in this defense, a carefully worded discussion allowed her to wish with increasing desire that she could do the various things the author outlined as he detailed possibilities for the entire weekend.

When the mother seemed to have reached the right degree of emotional readiness, the question of her weight was raised for disposal. She was simply assured that she need not take medical opinion at all but would learn from her son on the morrow that her weight would be inconsequential to him. In fact it would take all of her strength, dexterity, and alertness in addition to her weight to master the situation. She might even lose the contest because of the insufficiency of her weight. (The mother could not analyze the binding significance of this argument so simply presented to her. She was placed in the position of trying to prove that her weight was really too much. To prove this, she would need her son's cooperation, and the author was certain that the boy's aggressive patterns would preclude any passive yielding to his mother's weight. In this way the mother would be taught by the son to disregard her defenses against the author's suggestions, and she would be reinforced in her acceptance of those suggestions by the very violence of his behavior.) As the mother later explained, "The way that bucking bronco threw me around, I knew I would have to settle down to serious business to keep my seat. It just became a question of who was smarter, and I knew I had a real job to do. Then I began to take pleasure in anticipating and meeting his moves. It was almost like a chess game. I certainly learned to admire and respect his determination, and I got an immense satisfaction out of frustrating him as thoroughly as he had frustrated me.

"I had one awfully bad time though. When we came back from the bathroom, and he started to lie down on the floor, he looked at me so pitifully that I wanted to take him in my arms. But I remembered what you said about not accepting surrender because of pity but only when the issue was settled. That's when I knew I had won, so I was awfully careful then to be sure not to let any pity come in. That made the rest of it easy, and I could really understand what I was doing and why."

A LATER REINFORCEMENT

For the next few months, until midsummer, all went well. Then for no apparent reason except an ordinary quarrel with his sister settled unfairly to her advantage, Joe declared quietly but firmly that he did not have "to take that kind of stuff." He said he could "stomp" anybody, particularly the author, and he dared his mother to take him to see the author that very evening. At a loss what to do, his mother brought him to the office immediately. As they entered, she declared somewhat inaccurately that Joe had threatened to "stomp" the author's office. Joe was immediately told, disparagingly, that he probably could not stomp the floor hard enough to make it worthwhile. Irately, Joe raised his foot and brought his cowboy boot down hard upon the carpeted floor. He was told, condescendingly, that his effort was really remarkably good for a little eight-year-old boy and that he probably could repeat it a number of times, but not very many. Joe angrily shouted that he could stomp that hard 50, 100, 1,000 times if he wished. Reply was made that he was only eight years old, and no matter how angry he was he couldn't stomp 1,000 times. In fact he couldn't even stomp hard half that number of times, which would only be 500. If he tried, he would soon get tired, his stomp would get littler and weaker, and he would have to change off to the other leg and rest. Even worse, he was told he couldn't even stand still while he rested without wiggling around and wanting to sit down. If he didn't believe this, he could just go right ahead and stomp. When he got all tired out like a little boy, he could rest by standing still until he discovered that he could not even stand still without wiggling and wanting to sit down. With outraged and furious dignity Joe declared his solemn intention of stomping a hole in the floor even if it took a hundred million stomps.

His mother was dismissed with instructions that she was to return in the "square root of four," which she translated to mean "in two hours." In this way Joe was not informed of the time when she would return, although he recognized that one adult was telling another a specific time. As the office door closed upon his mother, Joe balanced on his right foot and crashed his left foot to the floor. The author assumed a look of astonishment, commenting that the stomp was far better than he had expected of Joe, but he doubted if Joe could keep it up. Certainty was expressed that Joe would soon weaken, and then he would discover he couldn't even stand still. Joe contemptuously stomped a few more times before it became possible to disparage his stomp as becoming weaker.

After intensifying his efforts, Joe reached a count of 30 before he realized that he had greatly overestimated his stomping ability. As this realization became evident in Joe's facial expression, he was patronizingly offered the privilege of just patting the floor 1,000 times with his foot, since he really couldn't stand still and rest without wiggling around and wanting to sit down. With desperate dignity, he rejected the floor-patting and declared his intention of standing still. Promptly he assumed a stiff upright position, with his hands at his sides, facing the author. He was immediately shown the desk clock, and comment was offered about the slowness of the minute hand and the even greater slowness of the hour hand, despite the seeming rapidity of the ticking of the clock. The author turned to his desk, began to make notes in Joe's case record, and from that he turned to other desk tasks.

Within 15 minutes Joe was shifting his weight back and forth from one foot to the other, twisting his neck, wiggling his shoulders. When a half-hour had passed, he was reaching out with his hand, resting some of his weight on the arm of the chair beside which he was standing. However, he quickly withdrew his hand whenever the author seemed about to look up to glance reflectively about the room. After about an hour the author excused himself temporarily from the office. Joe took full advantage of this, and of several repetitions, never quite getting back into his previous position beside the chair.

When his mother knocked at the office door, Joe was told, "When your mother comes in, do exactly as I tell you." She was admitted and seated, looking wonderingly at Joe as he stood rigidly facing the desk. Signaling silence to the mother, the author turned to Joe and peremptorily commanded, "Joe, show your mother how hard you can still stomp on the floor." Joe was startled, but he responded nobly. "Now, Joe, show her how stiff and straight you can stand still." A minute later two more orders were issued, "Mother, this interview between Joe and me is a secret between Joe and me. Joe, don't tell your mother a single thing about what happened in this office. You and I both know, and that's enough. O.K."

Both Joe and his mother nodded their heads. She looked a bit mystified; Joe looked thoughtfully pleased. On the trip home Joe was quiet, sitting quite close beside his mother. About halfway home Joe broke the silence by commenting that the author was a "nice doctor." As the mother later stated, this statement had relieved her puzzled mind in some inexplicable way. She neither asked nor was given any explanation of the office events. She knew only that Joe liked, respected, and trusted the author and was glad to see him occasionally in a social or semisocial fashion. Joe's behavior continued to be that of a normal, highly intelligent boy who now and then misbehaved in an expected and warrantable fashion.

Two years passed, and Joe's mother became engaged. Joe liked the prospective stepfather but asked his mother one demanding question—did the author approve of the man? Assured the author did approve, there was then unquestioning acceptance.

COMMENT

In the process of living the price of survival is eternal vigilance and the willingness to learn. The sooner one becomes aware of realities and the sooner one adjusts to them, the quicker is the process of adjustment and the happier the experience of living. When one knows the boundaries, restrictions, and limitations that govern, then one is free to utilize satisfactorily whatever is available. But in an undefined world, where intellectual and emotional fluctuations create an enveloping state of uncertainty that varies from one mood and one moment to the next, there can be no certainty or security. Joe sought to learn what was really strong, secure, and safe, and he learned it in the effective way one learns not to kick a stone with the bare foot or to slap a cactus with the bare hands. There are relative values of effort and purposes and rewards, and Joe was given an opportunity to strive, think, assess, compare, appraise, contrast, and to choose. Thereby he could learn and hence could adjust.

Joe is not the only patient on whom this type of therapy has been employed. Over the years there have been a number of comparable instances, some almost identical. In some of these cases the author's practice of keeping in contact with patients over the years has yielded information repeatedly affirming the value of reality confrontation as a successful measure for defining a secure reality.

The Hypnotic Corrective Emotional Experience

Milton H. Erickson

Reprinted with permission from *The American Journal of Clinical Hypnosis*, January, 1965, 7, 242-248.

An unintentional, completely hypnotic, Corrective Emotional Experience occurred under unusual circumstances at a medical meeting where the author had been asked to present a general lecture on hypnosis without a demonstration. In attendance there was a group of seven physicians, among them psychoanalytically trained psychiatrists, who sat together in the rear to one side of the auditorium. They had previously spoken most adversely about hypnosis and had opposed inviting the author to address the group. Scattered in the audience were a number of other physicians who were also unreceptive of hypnosis, a fact of which the official host for the meeting had informed the author. During the question-and-answer period numerous requests were made that a demonstration of hypnosis be given. Since it was obvious that the vast majority of those present were decidedly in favor of a demonstration, volunteers were called for—but there were none. The author asked if the audience would be agreeable to his choosing at random someone in the audience, and a most favorable response was received. Thereupon a physician was singled out and invited to the speaker's platform. After a moment's hesitation he rose and strode up briskly. As he was doing this, the author's host frowningly shook his head negatively and held up his hand in the "thumbs down" position to indicate that a bad choice had been made. But the author saw no immediate solution to the problem.

(Two explanatory paragraphs will be inserted here so that the reader may better understand the unexpected course of events. After the meeting the author was apprised that his subject was a rather unusual and even somewhat eccentric character. He had never married, and had two interests—his medical practice and his studies. He was a man of high intelligence and integrity, and he was well-respected. He had intensely strong, even extreme likes and dislikes, and he was not hesitant about making them freely and bluntly known. For years he had been bitterly resentful toward psychiatry, and the author's random choice of him as a subject caused considerable apprehensiveness in the audience.

As for his "studies," he was always engaged upon some new course of intensive study which was invariably detailed, comprehensive, and systematic, and which he always completed. Usually with the advent of any new or striking development in medicine, he embarked upon an intensive course of study for months at a time, yet devoted himself untiringly to his extensive general practice in a large rural community. Because he was extremely well informed, he was frequently consulted by physicians in other fields—except psychiatry, toward which he manifested a well-verbalized, violent dislike. Also he often freely exhibited unreasonable antagonism toward psychiatrists in general. Even his presence at the lecture had distressed a number of people, who anticipated a disagreeable

outburst from him. The author's chance selection of him as a subject caused those in charge of the meeting serious alarm, but they could think of nothing to do to avert the expected catastrophe.)

As the man approached the author at the podium, he was asked for his name. His reply was simply the rather brusque question, "Is it really necessary for you to know my name to demonstrate hypnosis?"

He was answered with the statement, "Not at all; just seat yourself comfortably in that armchair while I make a few remarks to the audience." After a momentary pause he moved the chair so that he would face the author and present his profile to the audience; then he sat down. Addressing the audience, the author reminded them of his comments earlier on ideomotor responses, their involuntary character, and the frequent development of a sense of physical dissociation. Peripheral vision disclosed the subject to be listening with utter intensity. The author continued with an explanation that a voluntary motor response, once initiated, could be converted easily into an involuntary continued response. "For example," it was stated, "if I take this physician's wrist and extend it at shoulder level in front of him [suiting action to the words], and then gently, with my right hand, place his hand in a position of dorsiflexion [again suiting action to the words], and ask him to fixate his gaze intently on his thumbnail, and begin the action of moving his hand slowly toward his face [doing so], his elbow will bend gently more and more, and the movement soon becomes involuntary [releasing the hold upon the wrist with a wavering, uncertain, altering, and constantly decreasing pressure of first one finger and then another until, unnoticeably, contact with his wrist ceased, a technique described in a previous article (Erickson, 1964)], and there results an unexpected catalepsy and the rather rapid development of a deep trance state."

It was at once apparent that exactly what the author had just described was occurring, since this procedure is an indirect, unchallengeable technique seemingly addressed to others, but which puts the subject in the position of listening and trying to understand and thus becoming responsive by virtue of the very effort of trying to understand, thereby to be enabled to challenge the operator. But most astonishingly, as the subject's hand slowly approached his face, he slowly twisted his body and tilted it forward until he seemed to be in a position to look directly at the group of hostile physicians in the far corner of the room. As his hand came close to his face, there was a slow spreading of the digits, the development of a slightly amused, sardonic expression on his face, and his hand came to rest in the nose-thumbing position. At a total loss to understand this behavior, the author simply watched him for at least three minutes. The man was obviously cataleptic, his blink and swallowing reflexes were absent and no startle response was manifested when the author surreptitiously pushed a heavy pointer off the table to fall noisily on the floor. The audience, however, showed an over-reactive startle response to this disturbance, but the author merely attributed this to the unusualness and rigidity of the subject's behavior they were witnessing.

At a loss to understand the situation, the author addressed the subject and instructed him to lean comfortably back in his chair, to let his hand slowly lower until it rested

comfortably in his lap, to understand fully that henceforth, whenever he wished, he could go into a profound somnambulistic trance, and to take three deep breaths slowly and then to awaken with an amnesia for having been in a trance.

The subject responded as instructed, but immediately upon awakening, he said most earnestly, "Dr. Erickson, I owe you an apology. I came up here for only one reason, to prove that hypnosis is a fraud, a miserable hoax. That's why I didn't tell you my name. It's W——, but all my friends call me Jim, so just call me Jim. Then, when you asked me to sit down on the chair, I began to do some fast thinking, I went into high speed and I realized that all the things you said here tonight made complete sense. The trouble is, I've been too busy listening to a bunch of blowhards [nodding his head toward the far corner of the room] that I didn't like anyway and actually believing what they said about hypnosis, when all the time they were just showing off their ignorance. I'm a very intolerant man when it comes to somebody shooting off his mouth about something he doesn't know a thing about, and should keep his mouth shut and his mind open. And when I sat down in this chair, I realized that I was doing the same thing toward them [again nodding his head toward the far corner of the room] that they were doing toward you, and I was joining them. But I didn't come up here to tell you this, I just want you to know I'm sorry for being rude. And now I'm ready to learn everything you can teach me. What stuns me is how fast what you said tonight has sunk in. And next I'm going to apologize to those fellows [nodding his head indicatively a third time] for being so close-minded and learn from them everything they can teach me. And Mister, I sure mean that—you don't know what I'm talking about but everybody else here probably does. Now with that off my chest,
I'm pleased to be your subject, you can be sure I'll try to cooperate."

The author made no effort to understand this explanation but simply asked him if there were any special technique he would like used. He answered, "Mister, I don't know a thing about techniques, so use some technique where I can sort of look in and see what's happening."

"In what field of medicine do you practice?"

"Well, I do a lot of general medicine, but I do a lot of anesthesia for my colleagues, so that would be interesting."

"Local or general?"

"Oh, you mean me—that is, what kind of anesthesia? Well, it would have to be local if I get to look in on it in me."

During those questions and answers the author's study of the patient disclosed him to be in a somnambulistic trance. Turning to the audience, the author stated that the situation they had just witnessed was marked by an actual continuation of the somnambulistic state, despite the subject's apparent state of waking awareness; that the subject's interest in hypnosis was obviously so great that his desires would literally become self-

suggestions, and that the author would play only a minor part in the subject's development of hypnotic phenomena. In fact, the specific request for anesthesia would become manifest in accord with previously observed behavior, and suggestions would not be necessary. As this was said, the author took advantage of his standing position, which shielded his right arm, and as he said the words, "It will be here," the author drew attention to his right arm by moving it. Neither the audience nor the subject grasped the meaning implied, and the subject said, "I don't follow you at all." He was told, "It's all right, you will."

The subject answered, "I still don't get it, but something is happening to me. Look, Mister, I mean Dr. Erickson, that's just a speech habit of mine, especially when I'm excited, but look Mister, there I go again, but my whole right arm is numb. In fact, I can't even feel it being there. I can see it hanging there, but I can't move it, and look, I can't even feel this [pinching the back of his right arm vigorously]. Now you haven't hypnotized me, how come I've got an anesthesia of the arm? I don't understand this." The author gave the following explanation, apparently addressed to him but which was actually intended to inform the audience. "A few minutes ago the audience watched right arm behavior. You wished to have a local anesthesia. The previous arm behavior [the ideomotor activity] set up a pattern or focus for further hypnotic behavior. There was really no awakening from that trance by you, only the continuance of a profound somnambulistic trance, which often occurs in highly intelligent, vitally interested subjects. As can be noted, your blink reflex has been continuously absent as has been the swallowing reflex. Additionally, despite the fact I am addressing the audience, your behavior is entirely in response to me without a single glance in the direction of the audience, since you [a nod of the head similar to that the subject made previously] are out of rapport with them. Hence, there isn't any turning toward or attention directed to the audience as I speak, which would be so natural in the waking state. You are looking to me only for a resolution of the obvious confusion expressed by your face."

The subject spoke, "Mister, I just don't get you at all. I just don't know what you are talking about. What I'm interested in is this arm anesthesia. I've got an old lady with cancer, and this anesthesia I've got in my arm is the thing she needs for her pain. Oh, Ruth, Ruth." Previous comparable experience allowed the author to recognize immediately what had happened; the subject was promptly asked for the benefit of the audience, "By the way, where are we?" The reply startled the audience, "Oh, didn't I tell you? This is my office, and the girl will bring in the record on the old lady with the cancer."

A few questions clarified for the audience that in the subject's intense interest in hypnosis and in his earnest desire to seek information, he had spontaneously reoriented himself to his office, his favorite place to study.

By intruding upon the subject's wishes, the author was enabled to have him demonstrate all of the various phenomena of deep somnambulism to the satisfaction of the severest critic in the audience. Nobody questioned the validity of the hypnotic responses.

At the conclusion of the demonstration the subject was dismissed with the statement that he could now awaken from the trance, that he could remember any and all of his trance experiences if he so wished, that he could develop a trance state whenever he wished, and that he could now return to his seat in the audience. He aroused, started to leave the stage, paused, turned excitedly, and declared, "Listen! You've had me hypnotized. I'm remembering a lot of things. I didn't know you did that! That anesthesia was certainly real. And I am interested! I do have an old lady with cancer. Maybe I can do something for her besides narcotizing her."

As a final demonstration the author asked, with special intonation, "And you can develop a complete amnesia for everything, can you not?" His response was an immediate development of a trance, whereupon the author in a casual tone of voice said, "Fine, thank you very much, that's all except that Louis [the author's host] might want to ask you if you can go into a trance."

The subject aroused immediately, whereupon Louis asked him, "Jim, do you really think you could go into a trance?"

The answer was, "Well, this afternoon I was completely certain that hypnosis was a lot of hocus pocus, but after the lecture tonight and the thinking I've done, I'm completely certain it's psychosomatic interrelationships that are definitely applicable in various medical conditions, and I can promise you that I'm going to make a sufficiently intensive study so that I can convince those fellows back there" —nodding his head toward the hostile group. "But first I want Dr. Erickson to induce a trance in me and let me experience some hypnosis, and then, Mister, I'm going to get every book on hypnosis that Dr. Erickson recommends, some good books on psychology that Joe [indicating a member of the audience] can recommend. And [smiling broadly] I'll have those fellows back there recommend some books on psychiatry and psychosomatics and I'll get out my anatomy and neurology texts, and Mister, I'm going to have me a time, and when I finish, I'll know something about hypnosis, and then I'm going to see how hypnosis fits into medicine the way it should be practiced."

Upon leaving the stage, Jim strode to the back of the room and shook hands cordially with each of the special group. In the general discussion that followed Jim discovered that he could recall all of the events of the trance and forget them practically at will. This intrigued him as greatly as it did the audience.

In the time that has elapsed since then, well over a year, Jim has followed his plan of study, and now uses hypnosis extensively in his general practice. Of remarkable note was the fact that Jim's long-continued resentment toward psychiatrists and psychiatry, so much in evidence for years, vanished that evening in the hypnotic state. Warm professional friendships and a new view of a medical specialty resulted from that apparently unintentionally developed Corrective Emotional Experience in the hypnotic state.

DISCUSSION

The foregoing account is an excellent example of a Corrective Emotional Experience hypnotically induced. The situation in its setting and nature made it easy to describe and explain. It demonstrates additionally the unimportance of the therapist's complete awareness of everything without being necessarily handicapped in directing or aiding the patient's progress. It clearly illustrates the need and the value of actual behavior in enabling a patient to make therapeutic progress. Also of importance was the author's unconcerned acceptance of the patient's behavior and his utilization of the total setting and the patient's behavior as measures of indirectly suggesting an interweaving and an integration of the forces governing the patient. Addressing remarks to the audience and to the patient—actually separately, though simultaneously, by having the choice of words convey one meaning to the patient and another to the audience—is always a most effective means of promoting therapy. In his many lectures before the professional public the author has many times deliberately undertaken therapy for patients not seen previously, but who "volunteered" as "demonstration subjects." In the guise of suggestions leading to the demonstration of hypnotic phenomena, therapeutic suggestions can be indirectly given without the audience becoming aware of the pertinences to the subject. Subsequent inquiries have disclosed that many corrective emotional experiences on the lecture platform have been of sustained value. Often, too, the author has found out that the "volunteering" as a "demonstration subject" is a trial by the patient, to test for himself his readiness to accept therapy with subsequent good results.

For example, a woman who was a lifetime enuretic "volunteered" as a demonstration subject. Just previous to the demonstration she had been asked in the waking state if there were anything she wished the author to do. She stated that a physician friend of hers in the audience was particularly interested in enuresis in small children, and as the author turned to the audience, a physician nodded his head affirmatively. Nevertheless, the author, being a psychiatrist, wondered if there might be a more personal application to the requester. With subtle but strong emphasis, he asked the woman, "Do *you* mind if *I discuss* this matter *helpfully with you here* on the platform?" She answered agreeably, but a slow flush covered her face, not deeply enough to be apparent to the audience.

Juvenile enuresis was discussed at length with various careful emphases while the woman went into a trance, and she was then used as a demonstration subject immediately after the discussion of enuresis.

Two years later, while lecturing there again, the same woman was noted to be present. She was sought out and taken aside and asked if she wished to volunteer again. She replied simply, "No, not really. I don't need to now." The implication of this last statement suddenly became apparent to her. She flushed deeply and hesitantly said, "You knew, didn't you?"

"Yes, but tell me, please, what happened."

"As you discussed it, I knew that you were talking to me as well as the audience, and I sat in frozen horror because I knew one little slip of your tongue would expose me to the

audience. It was horrible. I guess I went into a trance to escape. Then when you finished discussing it, you explained a posthypnotic suggestion in which you told a patient that it was over with and done with, and belonged to the past, and to go on to other and pleasing things. I knew you were saying that to me; and my horror and terror disappeared, and I felt so happy and relieved and comfortable. Then you began demonstrating things, but I just felt like I was in heaven. And that was the end of it—that horrible terror, that sudden feeling of peace and comfort, and the end of my problem. I don't understand. I don't want to understand. I'm just happy. Many, many thanks to you."

Many other instances of a Corrective Emotional Experience could be cited, since the author utilizes it in psychotherapy extensively. Why and how it serves the individual's needs is usually difficult to understand. Sometimes it is used without employing hypnosis, but this is more difficult. Hypnosis allows freedom and ease in structuring the therapeutic situation and renders the patient much more accessible. Also, hypnosis allows ready retreat if the patient is not yet ready, without there being any loss of therapeutic gains already made. One can easily and safely reinterpret a structured Corrective Emotional Experience for which the patient is not yet ready, and thus leave the way open for a future approach. The Corrective Emotional Experiences vary in relation to the individual and in relation to his problem. The essential task is to structure the therapeutic situation in such fashion that emotions are greatly intensified, all behavior inhibited, and the need for behavior intensified. Then, and not until then, an opportunity for directed behavior with a special significance is given.

In the case of the physician reported above, the author was aware of a difficult situation from the "thumbs-down" signal, and was then made more acutely aware of it by the challenge in the refusal by the volunteer to give his name.

If the readers will review the handling of this situation, they will note an immediate inhibition of the physician by instrumentalizing him as a display object for the audience, the initiation of passive directed behavior, the careful shifting of the intense emotional state that the man already had into an intense emotional interest in his own subjective experience, which he himself augmented by his intense emotional interest in his cancer patient. This was followed by a redirection of his interests toward his colleague Louis, which, perhaps unnecessarily, intensified his behavior in relation to his other colleagues. Thus, a very marked reorientation of this physician in his life situation and his total life adjustment was effected by simple little items of behavior which he progressively enlarged into a revision of his emotional and intellectual attitudes.

As for the enuretic woman, she became hopelessly trapped by the author's clinical attentiveness, and rapidly led in a terrifying, bewildering, threatening sea of emotions, inhibited in all of her behavior and helpless until suddenly she was propelled into doing *the things the author wanted her to do*, and doing these things well and competently. This created a feeling and an attitude which she carried over into the field of her enuresis problem, where, without explicitly so declaring, she wanted the author's aid to tell her to do well and competently the things that she knew the author would tell her to

do. Thus, a long-continuing pattern of behavior was set into action, tremendously reinforced by the woman's own emotional history.

In brief, the Hypnotic Corrective Emotional Experience, however simple it may appear, is a highly complex restructuring of subjective understandings of one's subjective experiences that can be initiated very simply and then gently guided toward a therapeutic goal. Essential is good clinical attentiveness to the patient's behavior, a confident awareness that one can delay, even halt, and nullify hypnotically whatever is taking place, and postpone, modify, or reinforce the structured situation leading to a therapeutic goal. More than once this author has found himself in the need of arresting the patient's behavior hypnotically in some distracting, harmless manner while he carefully revised his own understandings, thus to meet better the patient's needs.

What happens if a hoped-for Corrective Emotional Experience gets out of hand and becomes uncontrolled? Merely a disagreeable experience for the patient and properly increased awareness by the therapist of the problem at hand, with a need to repair rapport lest the patient seek help elsewhere. Even at the worst, the patient may be benefited by the debacle which serves to render the patient more aware of his needs. More than once this author has deliberately structured a Corrective Emotional Experience wrongly and watched the patient react unfavorably; and then, with carefully mended rapport, he began again, aided by the patient's unexpected unconscious wisdom in restructuring the corrective Emotional Experience. As for actual harm this can be best summarized by comments from patients, of which the following is an excellent example: Things really went all wrong there for a while, and that shook me awfully. I didn't think I could ever get straightened out, but then things would begin to slide together so smoothly, and I would begin to think that being so badly shook just kind of speeded things up."

In conclusion, the Hypnotic Corrective Emotional Experience is a relatively easy and effective psychotherapeutic measure in the hands of an attentive clinician. It is, as is illustrated in the instances cited, best "played by ear" with no elaborate plans formulated, but with a multitude of possibilities floating freely in one's mind ready for adaptation to each new development presented by the patient. It is easily arrested and nullified if not properly structured, and at the worst can only lead the patient to seek a more competent therapist. Used with care and discrimination, the Hypnotic Corrective Emotional Experience is of great value in shortening psychotherapy and in bringing about a therapeutic reordering of the patient's adjustments to his life situation.

Hypnotic Realities

The Induction of Clinical Hypnosis
and Forms of Indirect Suggestion

by
Milton H. Erickson, Ernest L. Rossi & Sheila I. Rossi

With a Foreword by Andre M. Weitzenhoffer

ACKNOWLEDGMENTS

We wish gratefully to acknowledge the help we received from the following friends and colleagues: Roxanne Erickson, Christie Erickson, John Hedenberg, Jack A. Oliver, M.D., Robert Pearson, and Kay Thompson.

OVERVIEW CONTENTS

ANALYTICAL TABLE OF CONTENTS

Foreword

For the many who never had the opportunity and never will have the opportunity to attend workshops led by Milton Erickson, this work will serve as an invaluable surrogate. Psychotherapists, in general, as well as hypnotherapists, will find the work rewarding reading and study, for Erickson is above all a psychotherapist, and his *modus operandi* transcends clinical hypnotism. As for academicians and researchers, I believe they will find enough food for thought and research here to keep them busy for some time to come.

My first encounter with Milton Erickson was in 1954 or 1955 at a meeting of the Society for Clinical and Experimental Hypnosis in Chicago. When I met him he was engaged in conversation with a small group of colleagues in a hotel lobby. I had never seen the man or even a photograph of him. Yet in a strange way, as it then seemed to me, as I saw him from some distance out of hearing range, I knew this was Milton Erickson. I have thought back to this incident a number of times. Conceivably I had heard somewhere that he had had polio and the fact he leaned on a cane might have been the clue to his identity. I cannot be sure, but I am inclined to believe the clues were more subtle. In a way, I had encountered Milton a number of times previously—through his writings which I had studied exhaustively. Through these, I had begun to appreciate the uniqueness of his person. I believe that some of the qualities which have made him the individual he is, were communicated to me through these writings, and that I experienced them more directly as they were manifesting themselves as he interacted with others.

In the years which followed I was to have other occasions, by far too few to suit me, to meet with him, watch him demonstrate, watch him doing therapy, and listen to him talk about hypnotism as well as other matters. More particularly, I had the opportunity to see why, as the years have gone by, he has grown into a quasi-legendary figure to whom the title of "Mr. Hypnosis" was once given. I have also had the opportunity to see in action such famed stage hypnotists of the forties and fifties as Ralph Slater, Franz Polgar, and others, many of whom billed themselves as "America's Foremost Hypnotist," the "World's Fastest Hypnotist," etc., and who extolled their fantastic prowess *ad nauseam.* Good entertainers, yes. As hypnotists, however, they came up poor seconds to Milton Erickson, and yet there never was a more quiet, unassuming man.

It is not surprising then that many professionals have tried to emulate him. None thus far have ever truly succeeded, although a few have managed to become a fair approximation. Some of the reasons for this become clear on reading this work. Some of these will still remain unclear. If the authors have failed to deal with them to the extent that their importance calls for, it is only because they are not exactly the kind of things one can adequately teach merely through the written word. Perhaps it is also because they are not teachable and, I suspect, there is some unwillingness on their part to admit this to themselves and the reader.

As the work makes it most clear, not only what one says to the patient or subject, how one says it, when one says it, and where one says it are all extremely important factors in the effective use of hypnotism, particularly in a clinical, therapeutic setting. It also becomes clear that one must view the hypnotherapeutic interaction in its totality and not piecemeal, and go even a step further by viewing it within the totality of its utilization. This takes the use of suggestion, and more broadly, of hypnotism out of the domain of the use of simple magic formulas and places it within the framework of the science of interactional and communication networks.

Erickson, however, is not just a master of verbal communication as the work makes evident. He is equally adept at non-verbal communication, which is one of the aspects to which the work does not and can not really do justice. This is unfortunate but unavoidable and certainly not an oversight on the part of the authors. One of the more memorable demonstrations of his skill at non-verbal communication that he has given in his career was in Mexico City in 1959 when he hypnotized and demonstrated various hypnotic phenomena

with a subject with whom verbal communication was impossible. He spoke no Spanish and the subject spoke no English. From beginning to end, communication was carried entirely non-verbally through pantomime.

I can personally attest to the effectiveness of his non-verbal communications, through an experience I had with Milton Erickson some 15 or 16 years ago. Here I think I should make it clear that, to my knowledge, I have never been hypnotized by him, at least formally. A group of us had met in Philadelphia with Milton, in a special seminar aimed at gaining some understanding of his *modus operandi.* One morning I was alone with him sitting at the breakfast table, facing him somewhat obliquely toward his left. As I recall, I was doing most of the talking. As I talked, partially absorbed in my thoughts, I became vaguely aware, peripherally, of Milton making peculiar repetitious gestures with one of his hands. Momentarily I made nothing of this, then with my awareness increasing, two things happened in very close sequence. My right hand moved out, spontaneous-like, to pick up the coffee pot which was on the table and begin to lift it. With this, the realization dawned on me that Milton wanted coffee. At that point, to use the terminology of this work, my "conscious mind" took over the action and I completed the act, while realizing now, that Milton's gesturing had, indeed, clearly spelled out a non-verbal request to have coffee poured into his cup. This sort of thing, as I learned in time, is one of his favorite ways of teaching or answering a question about a related matter. It is also his way of subtly testing an individual's suggestibility or hypnotizability. It is also his way of keeping himself in shape, so to speak. I said, toward the beginning of this paragraph, that I had never been "formally" hypnotized by Milton Erickson. True, if by "formal induction," we mean the use of any of the usual classical and semi-classical techniques described over and over in various texts on hypnotism. For reasons that will become clear presently, and certainly after reading the present work, I am sure that the authors would say that I had indeed been hypnotized by Milton at least on that particular occasion.

There is, of course, much more to effective verbal communication than saying words according to appropriate syntactical and other linguistic rules, or the introduction of appropriate non-verbal elements at the correct time and place. In my experiences with Milton Erickson, I have found that his control of such features as intonation and voice modulation, to mention only these two aspects, forms an intrinsic part of his approach to hypnotism. One has to hear and watch him to get the full flavor of his manner of speech. To say that he speaks gently yet incisively, slowly, calmly, softly, enunciating clearly and carefully each word, sometimes each syllable, the whole with certain cadence, can only give but a sketchy flavor of the process. There is, unfortunately, no way for a book to convey to the reader the kinds of information that would allow him to duplicate these features. However, attention can be called to this matter so that after studying the book, if the reader finds himself somewhat less effective than Erickson in spite of his efforts to do everything just so, he will not draw the wrong conclusions.

Another element which I believe enters into Milton's effectiveness and which, in my opinion, this work does not sufficiently bring out, is the quiet confidence, and strangely enough in view of his permissive approach, the authority too, that he exudes. There is a conviction expressed by his voice and his actions that everything is, or will be, as he says. Perhaps part of this exuded conviction has its roots in another feature of Erickson's interaction with his subjects and patients. As one watches him, one becomes very much aware of his ability to communicate to the subject and patient that he is participating in some of his experiences and sharing these with him. This is particularly evident when he elicits hallucinatory phenomena. As one witnesses Milton Erickson tell a subject about a skier "out there" on a distant snow covered hill which he describes in some detail, or about a rabbit "right down there at your feet-----and what color is it?" one often has the eerie feeling that he too

sees the skier, the hill, the snow, and the rabbit. How then, can the subject indeed fail to see them too? Whether or not Milton actually shares in the subject's subjective experiences, the impression is verbally and non-verbally communicated to the latter that he does. In my opinion this is an extremely powerful adjunct in his elicitation of the desired responses.

This is to say then, as a warning to readers who might expect much more than is reasonable from this work, that I believe there are important elements Milton Erickson brings to bear in his production and utilization of hypnosis which are not given as much attention as they deserve. This is not being written in a judgmental manner, an action hardly appropriate to a foreword. That aspect of the induction and utilization of hypnosis upon which the authors have chosen to focus is sufficiently complex and central as to justify certain omissions, particularly of material extremely difficult to deal with in writing.

Indeed, as every modern educator knows, the three major modes of communication, audio, visual, and written, each contributes in a unique and non-interchangeable way to the total process of education. What I have just stated merely reflects this fact. As written communication goes, the present work does a superlative job in elucidating the complexities of Erickson's approaches to clinical hypnotism. Indeed it accomplishes admirably that which can only best be done by the written word.

All of this leads me to one last point I would make for all those readers who would aspire to become another Milton Erickson. The book will teach them some of Milton's "secrets," which actually were never secrets at all. It is simply that what he did, and still does, was so obvious and natural to him that he assumed everyone knew what was going on. Whether knowing the secrets will be enough is a moot question. Milton did not become "Mr. Hypnosis" overnight. Many events and experiences have preceded his 50 years and more of experience with hypnotism. Many other events have filled these fifty years. Which ones have materially contributed to make the man, the hypnotist, and the clinician that he is? No one can really tell, even Milton himself. Some can be specified. Of these, some could be duplicated, some could not, and there are some which one would hardly want to duplicate. A wide experience with the phenomenology of hypnotism, especially in a naturalistic setting, extensive and long experience teaching, applying, demonstrating, and experimenting with hypnotism, all of these must be seen as undoubtedly having played an essential part in Milton Erickson's spectacular success. These are duplicable. Potentially duplicable by deliberate innoculation, but hardly the kind of experience anyone would readily undergo, is being stricken twice with poliomyelitis as Milton Erickson was. Certainly not duplicable is being born tone deaf and color blind. Erickson attributes much of his heightened sensitivity to kinesthetic cues, body dynamics, and altered modes of sensory-perceptual functioning to his life-long struggle with his innate and acquired infirmities. In his study and effort to mitigate these problems he acquired a personal awareness of altered patterns of functioning that was channeled into his life-work as healer. Additionally, Erickson has brought to his life-work a remarkable imagination and creativity, a high degree of sensitivity and intuition, a keen observing power, a prodigious memory for facts and events, and a particular ability for organizing what he experiences on a moment to moment basis. There is little here that can be duplicated on demand.

If one is not likely to ever be another Milton Erickson, one can at least learn something about his *modus operandi* and utilize it as completely as possible within one's own limitations and in terms of one's own personal assets. If this work does nothing more than help the reader accomplish this, it will have attained its purpose.

In approaching this work the reader should keep in mind that it is the product of pragmatists, and that it is specifically about therapeutic or clinical hypnotism, and neither about theoretical or experimental hypnotism. The reader might as well know from the outset that he will not find in this book any well defined and worked out theory, nor any solid scientific documentation of many stated facts. Quite clearly, the authors espouse a certain theoretical position with regard to the nature of hypnosis, of hypnotic phenomena, of suggestion, and of suggested behavior. One may or may not agree with them, and many alternative explanations will come to the reader's mind as he follows the authors' explanations of what takes place when Erickson makes a certain intervention or takes a certain step. However, to get the most out of this work, one needs to keep in mind that its focus is not so much upon developing a scientific theory as it is upon elucidating how Milton Erickson obtains the kinds of results that he does; results which most would agree involve behavior which may be labeled as being "suggested" and/or being "hypnotic." From a

practical, pragmatic standpoint it is relatively immaterial whether these elicited behaviors are "veridical," "role-playing," "a product of cognitive restructuring," involve some sort of "dissociative process," or are the consequences of a "shaping" process, and so on. Eventually, the "true" scientist wants to know what is what. This the authors have well recognized, often pointing out areas for investigation and suggesting experiments which could be made. But for the busy clinician and for the long suffering patient it is results, and quick ones at that, which count. Efficacity is the issue. For this reason effective hypnotherapists, which the three authors are, do not limit themselves to hypnotic procedures per se. On the contrary, as is evident from this book, and even more so from other writings of Erickson and of Rossi, effective hypnotherapy constantly interweaves the utilization of hypnotic and non-hypnotic behavioral processes. To take just one tiny example, the use of the "double-bind," be it as understood by Bateson, or in the special sense that the authors use it, is not a hypnotic technique or approach per se, nor does it involve a hypnotic or suggestion process, but it can be used as a specific tool to induce hypnosis and/or as a tool to elicit further behaviors from a hypnotized individual.

Although theory is neither the strength nor the focus of this book, a very definite theoretical position is reflected by Erickson's *modus operandi,* or at least guides it. It has been traditional, and this is still widely done, to view hypnotic behavior as behavior elicited by "suggestions" given while the subject is in a state of "hypnosis." However, even prior to Bernheim, and earlier, it has also been widely recognized that suggestions leading to the sort of behaviors exhibited by hypnotized individuals can also be effectively used in the absence of any induction of hypnosis. That is, they can be effective with persons who have presumably not been hypnotized. One interpretation of this observation, to which a small number of modern investigators have ascribed, is that hypnosis is not only unnecessary for the production of hypnotic behavior, but is also actually an unnecessary concept. This interpretation leads to the position there is no hypnosis as a state. However, one alternative to this position, and this is the one taken by the authors, is that all *bonafide* responses to suggestions are associated, *ipso facto,* with a hypnotic or trance state. From this standpoint there is no longer any distinction between "waking" and "hypnotic" suggestions, or if one prefers, between extra and intrahypnotic suggestions. To respond adequately to a suggestion is to be hypnotized. To put it a little differently, according to the authors, one cannot respond adequately to a suggestion without first, or at the same time, developing a hypnotic trance. This particular view of the situation comes about in a two-fold way: For the authors, if a response is to be an adequate response to a suggestion, it must be mediated by a different aspect of the mind than so-called conscious behavior. Thus they distinguish between behavior executed by the subject's "unconscious" and "conscious" mind. Normally, the conscious dominates the unconscious. The traditional inductions of hypnosis are nothing more or less than a freeing of the unconscious from conscious dominance, which is what they see as also momentarily existing any time an individual responds adequately to a suggestion. For them to function completely at the unconscious level is to be in a trance or hypnotic state, too. Any shift from conscious to unconscious functioning is a passage from a non-trance to a trance state ("waking" to "hypnotic state"). Although this will most likely be clear to many readers, it may be well to make the point here that the authors' conception of the "unconscious" is definitely not the one held by Freud. Morton Prince's "subconscious" is perhaps the closest to it. In any case it is an intelligent, complex level of mental functioning which appears to retain certain ego functions possessed by the conscious mind, while relinquishing, or not being affected by, some of the other functions usually associated with the ego.

One consequence of the above view of suggestion and hypnotism is that the notion of hypnosis as a state of hypersuggestibility becomes meaningless. To be suggestible is to be hypnotized. These are merely alternative ways of speaking of the same thing. It follows from this then, that it is also meaningless to speak of testing an individual's waking or non-hypnotic suggestibility, as a predictor of his hypnotizability. Finally, a formal induction of hypnosis, when it is successful, might be viewed in this framework as nothing more than an obtrusive technique which brings about a shift in degree of increased unconscious

participation in a step-like fashion. The real impact of viewing hypnotic and suggested behavior as the authors do, however, is to be found in the central topic of this work. How to facilitate, activate, cultivate, and, to some extent, utilize unconscious levels of functioning. This is what this book is about.

I have spoken at great length about Milton Erickson, and justifiably so, since this is a book about his approach to the therapeutic utilization of hypnotism. Still, this work is a joint effort and, had it not been for another of the authors, in particular, Ernest L. Rossi, it would never have seen the light of day. Rossi has done much more than record and report that which Erickson does and says. He has spent an enormous amount of time and effort getting him to explicate what has been so clear to Milton but so obscure to everyone else. Having done so, Rossi has proceeded to unravel, sift, analyze, translate, organize, and finally integrate what must at first have seemed to him to be a bewildering collection of data. This has been no small task, as I can attest to from my own unsuccessful past efforts to do something similar on a much smaller scale. Furthermore, Rossi has succeeded, I believe, in giving us an opportunity to see in a unique way, what Erickson does through the latter's very own eyes. Ernest Rossi's particular contribution does not stop there, however, *and* is to be further found in his compilation of interesting, useful, and thought provoking exercises, questions, commentaries and suggestions for research.

Finally, I believe that students of Erickson will find in this book answers to questions they wish they could have asked of him, but never did or could, and even more so, answers they sought but never got.

Hypnotic Realities

Introduction

This volume is the record of a unique demonstration by Milton H. Erickson of the art of inducing clinical hypnosis and the indirect forms of hypnotic suggestion. It is the record of a process of training and discovery. Initially, the senior author, Erickson, was involved in training the junior authors, the Rossies, in clinical hypnosis. As this training progressed, it became an analysis of the basic aspects of Erickson's work. Since the Rossies were beginners in the field, Erickson had to introduce and demonstrate the basic principles of clinical hypnosis in a manner that makes this volume suitable as an introductory text to the field. Since Erickson is such a creative innovator, however, much of the material will be of great interest to all psychotherapists, whatever their level of training or field of specialization.

It will be seen on the following pages that clinical hypnosis and therapeutic trance (using these terms synonymously) are carefully planned extensions of some everyday processes of normal living. Without quite realizing it, we all experience the "common everyday trance" wherein we are absorbed in a moment of inner reverie or preoccupation. During such periods we go about our daily routine somewhat automatically; much of our attention is actually focused inward as we experience ourselves a bit more deeply and possibly gain a fresh perspective or even solve a problem. Similarly, in the clinical utilization of trance we can be more receptive to our own inner experience and unrealized potentials in ways that are most surprising. With the help of a therapist's suggestions, these potentials may be explored and further developed.

The hypnotherapist shares many views in common with other well-trained psychotherapists: an understanding of the dynamics of unconscious processes in behavior; an appreciation of the significance of emotional and experiential learning as well as intellectual knowing; a high regard for the unique life experience of each individual; and so on. Hypnotherapists are different in practice, however, in that they are more specialized in the deliberate utilization of these processes within individuals to help them achieve their own therapeutic goals in their own unique way. In these pages Erickson demonstrates a myriad of approaches by which psychotherapists of all persuasions can facilitate psychological development with or without the formal induction of trance. He believes that trance itself is a different experience for every person; indeed, clinical trance may be understood as a free period in which individuality can flourish. From this point of view one comes to understand Erickson's work as an active approach to the basic endeavor of all psychotherapy: helping individuals outgrow learned limitations so that inner potentials can be realized to achieve therapeutic goals.

THE FORM OF THIS VOLUME

Each chapter begins with a carefully transcribed record of Erickson's induction of clinical hypnosis and his work with a subject along with a commentary to elucidate his procedures. His nonverbal behavior (gestures, pantomime, etc.) is described in parentheses. In these records there is some repetition of the procedures utilized, the questions asked, and the issues discussed. This repetition came about naturally because Erickson was engaged in training the Rossies in hypnotherapy. The Ros-sies frequently had to ask the same questions over and over to be sure they understood what Erickson was trying to convey. The repetition of similar themes in different contexts allows the reader to explore the significant features of Erickson's work and how he utilizes them in the contingencies of daily practice.

The induction section of each session is an extremely careful transcription of Erickson's exact words in boldface type. When he paused momentarily, his words are set off by a new line of type or by extra space between his words or phrases. When he paused for more than 20 or 30 seconds, it was indicated by the word "pause" in parentheses. Since this material

was recorded when Erickson was 72 years old on an ordinary cassette machine, there were a few occasions when some words were lost. This was carefully indicated with ellipses (. . .). The induction section thus provides the reader with the empirical raw data of Erickson's work unadulterated by anyone else's preconceptions. Erickson carefully read and approved of these transcriptions of his work. The induction section could thus serve as an objective record that other research workers could analyze in future studies of Erickson's approach.

The commentary sections, indented in ordinary type, are a discussion between Erickson (E) and Ernest Rossi (R) wherein Erickson explains his work with the subjects (S). The content of these commentaries was determined in equal parts by what Erickson felt to be the relevant material to be taught and by what Rossi felt he needed to ask in order to understand. These discussions were complex and sometimes drifted far from the issues at hand. For the practical purposes of publication, some of these discussions have been edited or paraphrased to make their meaning clear.

While some of these commentaries are thus slanted a bit through the lenses of Rossi's understanding and needs, they were also carefully read and sometimes modified by Erickson to emphasize a point here or clarify an issue there.

Each chapter ends with a number of sections by Ernest Rossi to clarify and elaborate on the relevant issues of Erickson's work just illustrated. At times Rossi attempts to analyze Erickson's clinical approach in order to uncover some of the basic variables that could be isolated and tested by future experimental work. These sections may be understood as an effort to build a bridge between the clinical art of Erickson's hypnotherapy and — the systematic efforts of the science of psychology to understand human behavior.

In studying this volume readers may do best by first reading the induction sections that are the "purest" indications of Erickson's work. Readers can then draw their own conclusions and ask their own questions about the work before progressing to the commentary sections. They can then determine for themselves the adequacy of the explications of the inductions. Readers may then write their own analyses of the relevant variables and perhaps test them, adding to the general knowledge.

At the end of each chapter or section where new material has been introduced, a number of graduated exercises are offered as a guide to aid hypnotherapists in developing their own skills in the clinical arts of observation, hypnotic induction, and the formulation of indirect suggestions. Many of these exercises will be of value to the general psychotherapist with or without the formal induction of clinical hypnosis.

This volume thus can serve as a heuristic, stimulating practicing psychotherapists to improve their own education and training. It also provides researchers with a clinical source of hypothesis about hypnotic phenomena and hypnotherapy that can be tested in a more controlled experimental fashion.

ONE

A Conversational Induction: The Early Learning Set

Dr. S was a psychologist and mother who was available to cooperate in a unique demonstration to ascertain if it was possible to train a professional person to become a hypnotherapist by having her learn by experiencing hypnosis personally. Dr. S had no experience with hypnosis apart from one demonstration where she experienced a short induction. This served to arouse her interest in the field, and she agreed to being tape-recorded in return for the free training she would receive.

Erickson initiates the process in this first session with what we may call the "Early Learning Set" induction. He simply requests that S focus on a spot while he talks with her. His approach is casual, gentle, warm, and friendly. Erickson simply talks about kindergarten and learning, imagery and comfort, the abilities of the unconscious and some alterations of the blink reflex. This is an example of conversational induction so innocuous and indirect that it is often difficult to recognize that trance is being induced. The impatient tyro waits in vain for him to begin the H*Y*P*N*O*S*I*S. Where are the mysterious manipulations that will take possession of the subject's mind and body? Where are the frenzy, prostration, stupor, and bizarre gesticulations that ancient medical lithographs have illustrated as possession and trance?

Modern hypnotherapy is quite different from the popular conception of hypnosis as a mysterious drama. Therapists are not showmen. They are, however, highly skilled in observation and can recognize even minor variations in behavior that provide important clues to the patient's interests and abilities. These clues are then utilized to help guide the patient into those interesting states of altered awareness that are generally called trance." Therapy then proceeds by "taking the learnings that the Person already has and applying them in other ways." Erickson is wary about suggesting or adding anything new to the patient; he would rather facilitate the patient's ability to creatively utilize and develop what he already has.

In this first session Erickson introduces a number of themes that will be repeated in ever-widening contexts in the later sessions: focusing the patient inward, freeing unconscious (autonomous) processes from the limitations of a patient's conscious sets, some principles and forms of indirect suggestion, and the ethics of trance and hypnotherapy. The beginning student in hypnotherapy often wants to learn everything all at once. That approach cannot really succeed. An understanding of the material develops naturally over time as Erickson goes over the fundamentals again and again in successive sessions. Frequently, the significance of the material in the early sessions is not entirely understood until later. Because of this, serious students may find themselves returning to restudy each session many times before it will be well understood.

Observation

E: Look at the far upper corner of that picture.

Now you (R) watch her face.

The far upper corner of that picture.

Now I'm going to talk to you.

(Pause)

E: So often the therapist does not even look at the patient's face. Yet changes in facial expression, muscle tonus throughout the body, and the breathing tell you how much of the patient's attention has been directed to the problem at hand. No sense in trying to work with a patient who's making restless movements.

R: The quieter the patient, the more he's directing energy to what is being said.

E: Yes! And you also notice whether the patient can be distracted from the therapy. Can the patient be disturbed by a bus outside or a siren? The less disturbed they are by such outer distractions, the more focused is their energy on therapy. You can only tell these things by carefully watching the patient.

Early Learning Set

When you first went to kindergarten, grade school,

this matter of learning letters and numerals seemed to be a big insurmountable task.

E: Now here you are merely taking the learnings that the person already has and applying them in other ways. But you're not creating anything new.

R: You're utilizing a learning set that already exists in the patient. It is a learning set that you're evoking by this particular induction.

E: Yes.

Truisms as the Basic Form of Hypnotic Suggestion

To recognize the letter A

to tell a Q from an O was very, very difficult.

And then too, script and print were so different.

But you learned to form a mental image of some kind.

You didn't know it at the time, but it was a permanent mental image.

R: You are using a series of very obvious truths, truisms, as suggestions here. As you speak of these early experiences, your words tend to evoke early memories and may facilitate an actual age regression in some subjects.

E: Yes. Suggestions are always given in a form that the patient can accept easily. Suggestions are statements that the patient cannot possibly argue with.

Internal Imagery

And later on in grammar school you formed other mental images of words or pictures of sentences.

You developed more and more mental images without knowing

you were developing mental images.

And you can recall all those images.

(Pause)

E: The average hypnotherapist says, "Look at this spot," and tries to focus the patient's attention to the spot. But it is easier to deal with the images the person has in his mind. There's a large variety of images in his mind, and he can slip easily from one to another without leaving the situation.

R: So internal imagery is therefore much more effective in holding attention.

E: Some external thing has no real value to them, but the images they have within are of value. Furthermore, you're only talking about what did occur in their past. It is their past and I'm not forcing anything on them. They did learn the alphabet, their numerals. They did learn many, many images. They can be pleased and select any image they want.

R: Far from arousing resistance, you're actually on their side in sympathy with them. You sympathize with their difficulty in learning, so you align yourself with the patient's difficulties.

E: That's right. And you know from your own experience it was hard.

R: With all that early accomplishment you're tapping, you also arouse their motivation for their current work in hypnosis.

Relations of Consciousness and Unconscious

Now you can go anywhere you wish, and transport yourself to any situation.

You can feel water

you may want to swim in it.

(Pause)

You can do anything you want.

E: This sounds like a great deal of freedom, but note I have given the suggestion to "transport" your consciousness to another situation. It can be any place you wish. It will probably be associated with water and you can do anything you want, but your consciousness need not be focused here in the therapy room.

Unconscious Functioning: Allowing the Conscious Mind to Withdraw

You don't even have to listen to my voice

because your unconscious will hear it.

Your unconscious can try anything it wishes.

But your conscious mind isn't going to do anything of importance.

E: The patient is not paying attention to me with his conscious mind, but the unconscious *will* pick up what I'm saying.

R: So your method gets directly to the unconscious without the intervention and distortion of consciousness.

E: Sometimes patients will later say, "I wish you had let me stay in the water or the garden longer."

R: So being in an "inner garden" is a way you have of holding their conscious attention. You're having their conscious attention focused on an internal image just as watching a spot focuses their attention on an outer image. But being absorbed in an internal image is much more effective for focusing attention.

E: Much more effective!

R: And while they are so absorbed, their consciousness is distracted so you can make suggestions directly to their unconscious.

E: They are far more interested in the conscious things. They are not paying attention to what I say consciously. They are paying attention unconsciously, so there is no interference from consciousness.

R: That's the important use of images: they bind a person's conscious attention while you make other (e.g., therapeutic) suggestions directly to their unconscious.

E: And it is very important for a person to know their unconscious is smarter than they are. There is a greater wealth of stored material in the unconscious. We know the unconscious can do things, and it's important to assure your patient that it can. They have to be willing to let their unconscious do things and not depend so much on their conscious mind. This is a great aid to their functioning. *So you build your technique around instructions that allow their conscious mind to withdraw from the task and leave it all up to the unconscious.*

R: You don't want them to have conscious control but to allow their unconscious to function smoothly by itself.

E: And then the results of that unconscious functioning can become conscious. But first they have to get beyond their conscious understanding of what is possible.

Eyelid Flutter:
Limiting Internal Responses

You will notice that your conscious mind is somewhat concerned since it keeps fluttering your eyelids.

E: Here I limited the fluttering to the eyelids rather than letting her generalize it into believing her whole system was fluttering or uncertain.

R. That slight, rapid, vibratory flutter of the eyelids during the initial phase of an induction is frequently taken as an indication of beginning trance.

Proving an Altered State

But you altered your rate of breathing.

You've altered your pulse.

You've altered your blood pressure.

And without knowing it, you're demonstrating the immobility that a hypnotic subject can show.

E: They don't know, but when you tell them they have altered their functioning, they can become aware of it. Their functioning is already altered so they cannot resist or deny it. They have their inner proof.

R: They have proof of an altered state. You inform the patient of these things to prove the hypnotic state rather than using a challenge.

E: That's right. I don't like to use the lack of the swallow reflex as a challenge because they tend to test that one. I'd rather use things they cannot test.

R: Because patients tend to swallow less during trance, some therapists have used it as a test of trance depth. They will "challenge" patients by telling them they cannot swallow. During the initial stages of trance training, however, such a challenge might actually arouse some patients.

Downgrading Distractions

There is nothing really important

except the activity of your unconscious mind,

E: That down grades traffic sounds or any other outside distractions without emphasizing that there are outside distractions. They can then apply this downgrading to whatever irrelevant stimuli that might be intruding.

R: You don't project your distractions on the patient and you don't even suggest there are distractions. But if there are distractions this phrase helps the person to downgrade them.

Implication and Illusory Freedom in the Dynamics of Suggestion

and that can be whatever your unconscious mind desires.

E: This is an example of what Kubie calls "illusory freedom." The person has a very great subjective feeling of freedom of choice, but actually I hold my subject to the task at hand through subtle directives and implications. For example, in the above I did say, "You can go anywhere you wish," but then I did define a place: water.

R: So the art of giving suggestions is to give careful direction, but you let the person have a certain illusion of freedom within the framework you have constructed.

E: When I earlier said, "Your unconscious can try anything it wishes," it sounds as if I were giving freedom, but actually that word "try" implies the opposite. The word "try" implies a block. You use the word "try" for your own purpose when you want to imply a block.

R: Use of the word "try" at that point actually blocked or tied up the unconscious until it received further directives from you.

E: Then when I say, "Your conscious isn't going to do anything of importance," it implies that your unconscious will do something of importance.

R: And the unconscious cannot do anything it wishes because you have already tied it up. In sum, this implies that the unconscious is going to do something important, and it's going to be what you suggest.

Not Knowing, Not Doing

Now physical comfort exists,

but you don't even need to pay attention

to your relaxation and comfort.

E: Notice how I emphasize "you don't even need." Patients drag along too much, so you emphasize all they don't need so energy can be focused on the task at hand.

R: This reinforces your earlier remark, "You don't even have to listen to my voice." It facilitates trance induction when the patient does not have to know or do anything.

Implication

I can tell your unconscious mind

that you are an excellent hypnotic subject,

and whenever you need to or want to,

your unconscious mind will allow you to use it.

E: "I can tell your unconscious" implies 1 don't have to convince your conscious.

R: In other words, *every sentence has implications, and it is in these implications that the important message is given*.

E: Yes!

Implication and Time

And it can take time its own time

letting you go into a trance

helping you to understand anything reasonable

E: You can take your time, but you are going to do it. That's the important implication. And they don't know how much time, so they have to rely on you.

Rapport

I can speak to you or anyone else I choose,

but only when I speak to you is it necessary for you to listen.

I can direct my voice elsewhere

and you will know I am not speaking to you

so you will not need to pay any attention.

E: Here I'm setting up a lot of freedom for myself in future work.

R: You are also giving suggestions for rapport wherein she will pay attention only when you are addressing her.

Signs of Trance

Dr. Rossi I think you see a lot of behavior of great interest.

The alteration of the blink reflex.

The alteration in facial muscles, the total immobility.

R: The slowing of the blink reflex before the final closing of the eyes and the relaxation of the facial muscles so the face has a smoother or "ironed out" expression are typical indications of trance.

Ethical Principle

R: Would you like to go on now and demonstrate more phenomena?

E: I might like to, but I did not discuss it with her consciously. Therefore if I go on I must first wake her up and ask her permission. The unconscious always protects the conscious.

Would you like to awaken now?

E: 1 cannot ask for permission to do something in trance while she is in trance. Asking for permission belongs to the normal state of awareness, and we must therefore ask while she is awake. You must be careful to protect the integrity of the personality and not exploit the trance state.

R: That would break trust and only arouse the so-called resistance.

Body Orientation on Awakening from Trance

[S opens her eyes and stretches a bit.]

Notice the body reorientation when she came back. Now, is there anything you want to tell us?

R. This reorientation to the body at the termination is another cue the therapist can use to recognize the patient has been in a trance. The stretching, blinking, shifting of body posture, yawning, wetting of lips, smoothing of hair, touching various parts of the body, etc., are all indications that the patient is reorienting from the trance to the awake state.

Perceptual Alterations: Eye-Fogging Phenomenon

S: Oh I enjoyed it, it was very peaceful. I was watching the point up there and it got foggy.

R: I see, a perceptual alteration.

R: This report of a fogging of the visual field is another fairly common indication of trance development. Others may report blurring, tunnel vision, alterations in the color of the background or the size and shape of things, etc.

Relaxation and Inner Absorption

S: I tried to listen in the beginning but then I went off onto my own thing. It would have been tedious to listen to you Dr. Erickson. I just felt like relaxing.

[After the tape recorder was turned off and the session had formally ended, S mentions her experience of "drifting" in the early stages of trance induction.]

R: Her relaxation and inner absorption to the point where she no longer made an effort to listen to you are further indications of trance. She was also following your earlier suggestion that she need not listen to your voice consciously because her unconscious could pick up what you were saying. She obviously was responding on an unconscious level since she did end her inner absorption when you told her to awaken.

OBSERVATION AND ERICKSON'S BASIC APPROACH

Observation is the most important aspect of the early training of the hypnotherapist. For Erickson this training began in youth and has continued through his life. Observation of the invariants and correlations in human behavior is the *sine qua non,* the stock-in-trade, of the creative hypnotherapist. The anecdotes and stories that Erickson tells on the following pages reveal him to be an acute observer of the regularities of human behavior. Erickson enjoys humor, and all of this original jokes are based on a sound knowledge of what people would do in a given situation.

As a child walking through the Wisconsin snow to school, for example, he delighted in leaving home early in the morning so he could set a crooked path on the straight roads of the flat plains and later observe how everyone who came after him followed his exact footsteps. People did not follow the straight road they knew was there; they apparently found it easier to follow the crooked path he made until he began to straighten it by cutting out some of the crooked loops on his later walks to school.

It is the regularities of behavior that are of great significance. These regularities are tools he uses to shape hypnotic phenomenon and behavior. Given a certain stimulus, it is useful

for him to know that a certain response will follow. Or, if he can evoke one piece of behavior, it is important for him to know that another piece of behavior is closely related to it and is likely to occur. Thus, he can use one stimulus to evoke a certain response and then use that response to evoke, by association, another specific response.

The situation is subjectively experienced as hypnotic when these responses appear to take place without conscious intention because patients are not aware of these predictable associations within themselves. Patients do not know all of the possibilities within their own behavioral repertory. Consequently, when they experience something that they could not have predicted (although the therapist can, because of his knowledge of the patients' behavioral associations), they assume the hypnotherapist somehow caused it. The hypnotherapist did arrange the behavioral situation so that a certain response by the patient would naturally follow. But the hypnotherapist was able to "cause" the response only by knowing how to utilize preexisting structures within the patient's behavioral matrix.
From this it follows that the more therapists know about the lawfulness of behavior, the more adequately will they be able to evoke desired responses in any specific situation. The more therapists are able to *observe* about the specific regularities of the individual patients, the more will they be able to facilitate therapeutic responses in those individuals.

Exercises in Observation

1. Look for and carefully study regularities in patients' behavior. These regularities can range from the mannerisms and rituals of saying "Hello" and adjusting themselves in the first minute or two to the therapy session to the habitual patterns in their associative structure when they talk about "problems." To what degree can you observe how a patient's problem is defined by a "closed circuit of associations," an habitual and invariant pattern of associations that the patient does not know how to break out of? What intervention can you make to help the patient break out? (Rossi, 1968, 1972a, 1973a).

2. Observe to what degree various patients are open and available to change and capable of following you and to what degree they are fixed, closed, unavailable for change—and actually expect you to follow them. Erickson looks for "response attentiveness" (the degree to which a person is absorbed in what another is saying) in assessing the degree to which a person would be a capable hypnotic subject. The more response attentiveness, the better the subject. We might therefore assume that the more a patient is open to therapist direction and the greater his capacity to be absorbed in what the therapist is saying, the greater his capacity as a hypnotic subject.

This requires that therapists focus on the "process" aspect as well as the "content," of their relation to their patients' behavior. Therapists who would become adept in hypnotherapy train themselves to observe the dynamics of "availability" and "following" in the transference-countertransference relation. The greater the openness and availability, the greater the following and capacity for hypnotic response. What helps a particular patient become more open and available to therapists? What can therapists do to make themselves more open and available to each patient?

We note that availability and following comprise a two-way street. The more sensitively therapists are capable of responding to patients' needs, emotions, and world view, the more will patients learn to be open and available to following the therapeutic suggestions. The more adequately therapists relate to their patients in the I-thou experience, the more relevant and therefore acceptable will their understanding and suggestions be.

3. The practical art of trance induction requires that therapists learn to observe behavior and tie suggestions to it. What changes are occurring in facial behavior? Does one observe a preliminary quiver of the eyelids? If so, then it can be suggested that the patient will soon blink his eyes. Is the blink reflex slowing? If so, the therapist can note it and suggest it will soon get slower until the lids finally close. When it is observed that the patient has just exhaled, that is the precise moment to suggest he take a deep breath. When it is observed that body movements are slowing, it can be suggested that the patient is becoming immobile

and will soon be completely quiet and comfortable. Therapists can become so conversant with suggestions that they can automatically associate the patient's manifest behavior with further suggestions. They gradually develop a flow of language that permits them to speak and reflect while carefully studying the patient's behavior to determine what is to be suggested next. One can practice such careful observation in many situations of everyday life. People in audiences and fellow passengers on a bus, plane, or train will be in a range of states from tenseness and alertness to trance. Learn to recognize the behavioral correlates of such states. In early practice inductions one can learn the art of observing behavior, commenting on it, and adding suggestions that will anticipate and further develop the behavior. In the sections that follow we will gradually introduce the various forms of indirect hypnotic suggestion that can be learned as one gains more experience.

THE CONSCIOUS AND UNCONSCIOUS IN CLINICAL HYPNOSIS

Erickson emphasizes certain aspects of the relations between the conscious and unconscious and the many ways of utilizing them for therapeutic purposes in his work with clinical hypnosis. This is a major theme that is introduced in this first commentary and will be discussed further in practically all the following sessions. We believe that consciousness, programmed by the typical attitudes and beliefs of modern rationalistic man, is grievously limited. It has been estimated that, at best, most people do not utilize more than l0 percent of their mental capacity. Most of us simply do not know how to utilize our individual capacities. Our educational system has taught us how to measure up to certain *external* criteria of learning only. We learn our A B C's, how to read and write, and similar skills. The adequacy of our learning is measured by our scores on standardized achievement tests rather than the degree to which we utilize our own unique neural circuits for our individual goals. Our educational system as yet has little or no means of training and measuring the individual's ability to utilize his own unique behavioral matrix and associative processes even though this *internal* ability is of the essence in creativity and personality development.

Consciousness is thus programmed to meet outer consensual standards of achievement, while all that is unique within the individual remains in abeyance. That is, most of our individuality remains unconscious and unknown. Erickson can say, "It is very important for people to know their unconscious is smarter than they are. There is a greater wealth of stored material in the unconscious."

Patients have problems because their conscious programming has too severely limited their capacities. The solution is to help them break through the limitations of their conscious attitudes to free their unconscious potential for problem solving.

Again and again we will find that Erickson's approaches to inducing trance and problem solving are usually directed toward circumventing the rigid and learned limitations of the patient's conscious and habitual attitudes. We will later demonstrate and discuss means of "depotentiating conscious sets," "coping with consciousness," and the like. All these phrases denote the same effort *to free individuals from their learned limitations.* As Erickson so clearly states, "You build your technique around instructions that allow their conscious mind to withdraw from the task, and leave it all up to the unconscious."

To implement this goal of freeing unconscious potentials from the limitations of consciousness, Erickson has pioneered the *indirect* approaches to hypnotic suggestion. These approaches are in marked contrast to most previous and current work in hypnosis, where *direct* suggestions are still considered to be the major therapeutic modality. The following sessions and commentaries will be a gradual introduction to these indirect approaches. So multifaceted and vast are the possibilities of these indirect approaches that Erickson has never been able to organize them into a comprehensive system; in fact, he does not always understand why and how they work. Indirect approaches are thus still a

virgin field, a terra incognita, that some readers will hopefully explore and extend further in their own research and therapeutic practice.

THE UTILIZATION THEORY OF HYPNOTIC SUGGESTION

We recently outlined the *utilization theory of hypnotic suggestion* as follows (F.rickson and Rossi, 1975):

> Trance is a special state that intensifies the therapeutic relationship and focuses the patients attention on a few inner realities; *trance does not insure the acceptance of suggestions.* Erickson depends upon certain communication devices . . . to evoke, mobilize and move a patient's associative processes and mental skills in certain directions to *sometimes* achieve certain therapeutic goals. He believes that hypnotic suggestion is actually this process of evoking and *utilizing* a patient's own mental processes in ways that are outside his usual range of intentional or voluntary control.

The effective hypnotherapist learns to use words, intonations, gestures, and other things that evoke the patient's own mental mechanisms and behavioral processes. Hypnotic suggestion is not a kind of verbal magic that can be imposed on patients to make them do anything. Hypnotic suggestions are effective only to the degree that they can activate, block, or alter the functioning of natural mental mechanisms and associations already existing within the patient. Erickson likes to emphasize that hypnotic suggestion can evoke and utilize potentials that already exist within patients, but it cannot impose something totally alien. Hypersuggestibility is not necessarily a characteristic of therapeutic trance as he uses it.

In his first published paper on hypnosis (1932) Erickson found that "hypersuggestibility was not noticed" as a necessary characteristic of trance. His work with 300 subjects involved in several thousand trances led him to this conclusion:

> Far from making them hypersuggestible, it was found necessary to deal very gingerly with them to keep from losing their cooperation and it was often felt that they developed a compensatory negativism toward the hypnotist to offset any increased suggestibility. Subjects trained to go into a deep trance instantly at the snap of a finger would successfully resist when unwilling or more interested in other projects. ... In brief, it seems probable that if there is a development of increased suggestibility, it is negligible in extent.

Erickson was not alone in this finding. In his review of the history of hypnosis Weitzenhoffer (1961, 1963, 1971) has pointed out that the earliest investigators (such as Bertrand, Despine, and Braid) did not view suggestibility as the essential feature of trance. It was Liebeault, and especially Bernheim (1895), who paved the way for viewing hypersuggestibility as a necessary condition for speaking of hypnosis or trance. This may have been accepted by modern experimentally oriented investigators (Hull, 1933; Hilgard, 1965) because it lent itself easily to the development of "hypnotic susceptibility scales," which were thought necessary for the quantitative study of hypnotic phenomena. Weitzenhoffer, however, has maintained the necessity of exploring the concepts of *trance* and *suggestibility* as separate issues.

For Erickson, trance and hypnotic suggestion are separate phenomena that may or may not be associated in any given individual at any given moment. Because of this Erickson (1952) has emphasized the difference between "trance induction versus trance utilization." In his early work he found it necessary to spend "four to eight or even more hours in inducing trances and in training the subjects to function adequately, before attempting hypnotic experimentation or therapy." The eight sessions of Erickson's work with Dr. S in this volume are thus a typical example of training a subject to experience trance. It will be seen that trance is a highly individualized process that can be experienced very differently even by the same person on separate occasions. For the therapeutic purposes of clinical hypnosis, however, we will focus our interest on exploring and facilitating only one particular aspect of trance. *We are interested in that therapeutic aspect of trance wherein the limitations of one's*

usual conscious sets and belief systems are temporarily altered so that one can be receptive to an experience of other patterns of association and modes of mental functioning.

Erickson views the separate issue of hypnotic suggestion as a problem in communication and utilization. To facilitate suggestion one must learn how to communicate more effectively. A major objective of this volume is to isolate the hypnotic forms of communication Erickson uses to facilitate suggestion. *These hypnotic forms are communication devices that facilitate the evocation and utilization of the patient's own associations, potentials, and natural mental mechanisms in ways that are usually experienced as involuntary by the patient.* Ordinary, everyday, nonhypnotic suggestions are acted upon because we have evaluated them with our usual conscious attitudes and found them to be an acceptable guide for our behavior, and we carry them out in a voluntary manner. Hypnotic suggestion, by contrast, is different in that the patient is surprised to find that experience and behavior are altered in a seemingly autonomous manner; experience seems to be outside one's usual sense of control and self-direction. *A successful clinical hypnotic experience, then, is one in which trance alters habitual attitudes and modes of functioning so that carefully formulated hypnotic suggestions can evoke and utilize other patterns of associations and potentials within the patient to implement certain therapeutic goals.*

The utilization approach to trance induction (Erickson, 1958, 1959) and the utilization of the patient's presenting behavior and symptoms as an integral part of therapy (Erickson, 1955, 1965b) are among Erickson's original contributions to the field of clinical hypnosis. This utilization approach, wherein each patient's individuality is carefully studied, facilitated, and utilized, is one of the ways "clinical" hypnosis is different from the standardized approaches of experimental and research hypnosis as it is usually conducted in the laboratory. It is in the clinician's ability to evaluate and utilize patients' uniqueness together with the exigencies of their ever-changing real-life situation that the most striking hypnotic and therapeutic results are often achieved. The utilization approaches achieve their results precisely because they activate and further develop what is already within the patient rather than attempting to impose something from the outside that might be unsuitable for the patient's individuality.

Most of the indirect forms of hypnotic suggestion that were pioneered by Erickson to facilitate his utilization approach were developed in clinical practice and field experiments without the benefit of detailed analysis or controlled experimental validation. In this volume, therefore, we will begin the process of analyzing a number of these indirect terms of hypnotic suggestion, first to achieve some understanding of their clinical application, and second, to propose research that will be needed to further explore their nature and use. In this chapter we will discuss "truisms" and "not doing, not knowing" as two of the most basic forms of indirect hypnotic suggestion.

TRUISMS UTILIZING MENTAL MECHANISMS

The simplest form of suggestion is a truism—a simple statement of fact about behavior that the patient has experienced so often that it cannot be denied. Erickson frequently talks about such psychological processes as if he were simply describing objective facts to the patient. Actually, these verbal descriptions can function as indirect forms of hypnotic suggestion when they trip off associated ideomotor and ideosensory processes that already exist within the subject (Weitzenhoffer, 1957); the truism can evoke and utilize the patient's own repository of life experience, associations, and mental mechanisms. The Generalized Reality Orientation (Shor, 1959) usually maintains these subjective associations and mental mechanisms in appropriate check when we are talking in ordinary conversation. When attention is fixed and focused in trance, however, the following truisms may actually trip off a literal and concrete experience of the suggested behavior.

1. You already know how to experience pleasant sensations like the warmth of the sun on your skin.

2. Everyone has had the experience of nodding their head "yes" or shaking it for "no" even without quite realizing it.

3. We know when you are asleep your unconscious can dream.

4. You can easily forget that dream when you awaken.

Practical experience demonstrates that evoking a subject's personal experience by way of a concrete image as illustrated in example 1 is an effective approach for evoking ideosensory experience. The "idea" of warmth and the image of the sun on the skin evoke personal associations from previous experiences that generate an actual "sensation" of warmth on the skin. In a similar manner, talking about a common life experience like nodding a head "yes" in example 2 is an "idea" that tends to evoke the actual "motor" response of head nodding. Such ideomotor and ideosensory processes were early recognized as the basis of many hypnotic phenomena (Bernheim, 1895), and they can be easily measured today with psychophysiological instruments. Many forms of biofeedback (Brown, 1974), for example, can be understood as ideosensory and ideomotor responses that are amplified and reinforced by electronic instrumentation. More cognitive processes like dreaming and forgetting can be facilitated when suggested by truisms that the average subject usually cannot deny, as in examples 3 and 4. This, then, is a basic mechanism of hypnotic suggestion: we offer simple truths that automatically evoke conditioned associations in a particularly vivid way. Suggestion is a process of evoking and utilizing potentials and life experiences that are already present in subjects but perhaps outside their usual range of control. Therapeutic suggestion helps patients gain access to their own associations and abilities to solve their own problem.

TRUISMS UTILIZING TIME

One particularly important form of truism is that which incorporates time. When Erickson makes a request for a definite behavioral response, he usually tempers it with time. He would never say, "Your headache is gone," because it might not be, and the patient would, with some justice, begin to experience a loss of belief. Instead, Erickson turns the direct suggestion into a truism by saying, "The headache is going to leave shortly." It could be a few seconds, minutes, hours, or even days. In a similar vein, the following suggestions all become truisms because the time factor allows patients to utilize their own associations and experience to make them true.

Sooner or later, your hand is going to lift [eyes close, etc.].

Your headache [or whatever problem] will disappear as soon as your system is ready for it to leave.

It probably will happen just as soon as you are ready. We will allow the unconscious to take as much time as it needs to let that happen.

Exercises with Truisms

1. Plan how truisms utilizing mental mechanisms and time can be used to facilitate trance induction and an experience of any of the classical hypnotic phenomena.

2. Do the same for any psychological function (e.g., memory, learning ability, time sense, emotional processes) your patient is interested in exploring for therapeutic purposes.

3. Make up verbal suggestions that can be used to alter body temperature, digestion, respiration, or any other psychophysiological function you have been trained to deal with in your professional work. It might be well first to write down these suggestions in a direct form

and then convert them into truisms utilizing time and common everyday descriptions of natural psychological and physiological processes.

4. Plan how truisms utilizing mental mechanisms and time can be used to help you cope with typical clinical problems you have been trained to deal with.

NOT DOING, NOT KNOWING

A basic aspect of trance experience is allowing mental processes to take place by themselves. We ask the subject to "relax and let things happen." Not doing is thus a basic form of indirect hypnotic suggestion that is of particular value in inducing trance. Most people do not know that most mental processes are autonomous. They believe they think by driving and directing their own associative processes. And to a certain extent they do. But it comes as a pleasant surprise when they relax and find that associations, sensations, perceptions, movements, and mental mechanisms can proceed quite on their own. This autonomous flow of undirected experience is a simple way of defining trance. Hypnotic suggestion comes into play when the therapist's directives have a significant influence in facilitating the expression of that autonomous flow in one direction or another.

When one is relaxed, the parasympathetic system is predominant, and one is physiologically predisposed *not to do* rather than to make any active effort of doing. Because of this it is very easy to accept the following suggestions for not doing during the initial stages of trance induction.

You don't have to talk or move or make any sort of effort. You don't even have to hold your eyes open.

You don't have to bother trying to listen to me because your unconscious can do that and respond all by itself.

People can sleep and not know they are asleep. They can dream and not remember that dream.

Not doing is a precondition for most hypnotic experience. Most hypnotic phenomena can be experienced by relaxing to the point where we simply give up our habitual patterns of control and self-direction. This is the opposite of the usual situation of everyday life, where we make concentrated efforts to remember. In trance we are congratulated for forgetting (hypnotic amnesia). In normal living we are enjoined to pay attention; in trance we are applauded for allowing the mind to wander (reverie, hypnotic dreaming). In daily affairs we are forced to act our age; in trance we achieve success simply by allowing a comfortable age regression to take place. In normal life we continuously expend strenuous effort to achieve veridical perceptions; in trance we allow sensory and perceptual distortions to take place and can even indulge ourselves in hallucinations. From this point of view we can understand how it is indeed much easier and enjoyable to experience trance than the extensive effort that is required to stay normally awake!

Thus, Erickson's initial direction in trance training is to help the subject have a comfortable experience in not doing. Frequently this can be experienced as momentarily losing abilities that are usually performed in an automatic and unthinking manner. Subjects can lose the ability to stand up or to keep a hand on the thigh. They can lose the ability to focus their eyes and see clearly; they can lose the ability to speak. How often in everyday life do we say, "I stood there like an idiot, unable to say anything or even think in that situation." That is an example of the common everyday trance where for a moment we were lost in not doing.

Closely related to not doing is *not knowing.* In everyday life we must continuously expend energy and effort to know. How pleasant, then, to find a situation where we can relax and do not need to know. What a relief! Most subjects can look forward to trance experience

as a newfound freedom from the demands of the world. They really don't have to know or do anything; their unconscious can handle it all by itself.

To help subjects realize this, Erickson frequently gives a preinduction talk about the conscious and unconscious—or the "front" and "back" part of the mind. He emphasizes how the unconscious is usually capable of regulating the body (breathing, heartbeat, all the physiological processes) and the mind all by itself. Indeed, people frequently have problems because their conscious mind is trying to do something that the unconscious can do better. He talks about infancy and childhood when one was "natural" and happy and *did not know.* At one time one did not know how to walk or talk or even make sense of visual and auditory impressions. One did not know that one's hand belonged to oneself, as when infants are observed to reach for their right hand with their right hand. Erickson frequently introduces puzzles and beguiling tasks to prove how amusing it can be when one does not know. He will ask if a person knows whether he is right- or left-thumbed. Few people do. He then asks people to put their hands behind their head and then fold their fingers together. The subjects then bring their folded hands to their lap to learn whether their left or right thumb is on top; that is the dominant thumb. Erickson then emphasizes how the patients' unconscious, their body, knew this all their life even though their conscious mind did not. With many anecdotes, stories, and interesting bits of behavior he carefully lays the groundwork to help patients realize and value the fact that the unconscious knows more and that the conscious can help best simply by relying upon the unconscious to do things. This permits subjects to adopt a receptive and acceptance set wherein they become more acutely sensitive to their own inner processes as well as the suggestions of the therapist.

Exercises with Not Doing and Not Knowing

1. Practice changing direct, positive suggestions into indirect suggestions of the "you don't have to" form. For example, instead of "Remain quietly seated with your eyes closed," one may say "You don't have to move or even bother keeping your eyes open," or "You can just remain comfortable and quiet and not bother with anything.")

2. Formulate suggestions for not doing and not knowing that are appropriate for the induction and maintenance of trance.

3. Formulate suggestions for "not doing" that will achieve interesting (a) hypnotic phenomena (catalepsy, anesthesia, age regression, etc.) and (b) psychotherapeutic goals (coping with phobias, compulsions, habits such as nail biting, smoking, overeating; self understanding, etc.).

TWO

Indirect Induction by Recapitulation

The indirect approach is a basic theme in Erickson's work and the source of a great deal of his originality. In this session he reveals his beliefs about how a patient learns to experience trance and illustrates many of his indirect approaches to suggestion. The therapist helps the patient learn to experience trance by depotentiating conscious sets and by creating a definite demarcation or dissociation between the trance state and the ordinary awake state. One of the major controversies in the past few decades of research in hypnosis has been between the traditional clinical view of trance as an altered state that is different and discontinuous from being awake versus the theories of trance as a special form of role playing (Sarbin and Coe, 1972), goal-directed imagining (Barber, 1972), or communication (Haley, 1963). There can be no doubt that Erickson maintains the traditional view of trance as a special state (Erickson and Rossi, 1974), but it is in his indirect approaches to suggestion that he is most innovative and nontraditional.

In this session Erickson illustrates with simplicity and seeming casualness a few cornerstones of the indirect approach: the yes set, implication, the double bind, and the use of truisms to align a patient's associative processes for creative trance work. He also illustrates indirect approaches for discharging resistance, utilizing personal motivation, and facilitating new learning and individuality. He takes some initial steps toward training Dr. S for the experience of dissociation, ideomotor signaling, hallucination, amnesia, posthypnotic suggestion, and the separation of conscious and unconscious processes. We witness a simple secret of the effectiveness of his approach: he *offers* suggestions in an open-ended manner that admits many possibilities of response as acceptable. Suggestions are offered in such a manner that any response the patient makes can be accepted as a valid hypnotic phenomenon. These open-ended suggestions are also a means of exploring the patient's response tendencies (the "response hierarchy" of learning theory and behavior therapy). The therapist can utilize these response tendencies to effect therapeutic goals.

Erickson begins this session with an indirect induction by recapitulation. He does not begin by directly asking the subject to recall and recapitulate experiences on the first session. Such a direct request would only evoke a plaintive, "But I don't know how." Instead, in the first sentence he utilizes her motivation for learning and then immediately touches gently but completely on many associations that will automatically evoke memories of her previous session and therefore tend to reinduce that trance.

Body Orientation for Trance

E: Both feet on the floor and your hands on your thighs, elbows at your sides.

Pick a spot here on this paper weight.

E: Here we exactly reproduce the previous hypnotherapeutic position. She went into a trance the first time with this position, so the position will help her to do the same now.

Reorientation to Trance by Recapitulation

Now the thing for you to do,

actually for your own education,

your own training,

your own experiences,

is to look at a spot there,

anywhere you wish,

and try to recall

what I said to you

and keep on

thinking,

trying to recall

the formation of mental images,

of letters, numbers

the unimportance of keeping your eyes open

and then permitting Dr. Rossi and me to talk

while you listen

and then beginning to drift away.

(Pause)

R: This is a fantastic sentence; it completely recapitulates the first hypnotherapeutic situation. You touch upon many associations to her previously successful hypnotic work and thereby facilitate your current hypnotic induction. You also deftly utilize her professional motivation by touching upon "for your own education." Instead of suggesting eye closure directly at this point, you prepare for it indirectly simply by mentioning "the unimportance of keeping your eyes open." I notice you use the word "drift" here, which she introduced at the very end last time to describe her subjective experience of entering a trance.

E: You always use the patient's own words and experience as much as possible for trance induction and suggestion.

Direct Suggestion for Inevitable Behavior

Your eyes can now close,

R: This direct suggestion for eye closure was now more appropriate since she had that fixed, glassy stare at this point. You only give direct suggestions when you're absolutely certain the patient is ready to accept them.

E: It is always safe to suggest behavior that is inevitable in the natural course of things.

Implication

and you will note

that the drifting can occur

more rapidly.

That there is less and less importance

to be attached to my voice

and that you can experience

progressively

(pause)

any kind of sensations you wish.

E: By emphasizing "more rapidly" you imply that drifting will occur.

R: Implication is thus a safe way of evoking and talking about behavior that may or may not be present. If you simply said, "You will now drift," that could arouse resistance.

E: For example, if I say, "I don't know what chair you are going to sit in ..."

R: That implies you will sit down; you are structuring their behavior, but so subtly that it's not likely to arouse resistance.

E: Another example: Will you pay by cash or by check?

R: By using the word "progressively" you throw the statement "you can experience" into an implication and then you pause to let it take place and the burden for it taking place rests with the patient.

E: And I pause with confidence that it will.

R: Further, it is a very safe statement to make because they are certainly experiencing some sensations. You give them permission to experience whatever they are experiencing and then take credit for evoking it.

E: That's right.

Early Learning Set

Bear in mind that when you first formed an image of the letter "A"

it was difficult.

But as you continued in school

you learned to form

mental images of letters and words and pictures

with increasing ease

until finally all you had to do

was to take a look.

(Pause)

R: You're evoking the early learning set again just as you did in the first session.

E: You imply that just as you overcame difficulties in the past, so you will now.

Limiting Attention and Downgrading Distractions

In the matter of experiencing other sensations

you learn to recognize cold

warm

muscle tension.

E: All these things are taking place in her body, so I am limiting her attention to herself and downgrading all outside distractions. By mentioning her "experiencing" I am referring to her own history. I am now evoking her personal history, and she knows it and cannot dispute it.

The "Yes Set"

In your sleep at night you can dream.

In those dreams you can hear

you see, you move

you have any number of experiences.

R: These are truisms about dreams. Your mention of "dream" tends to evoke partial aspects of the dream state as contributions to the current trance experience. I notice you frequently state obvious truths as if to evoke a yes set.

E: That's right! [Erickson here recounts how in his earliest experiences with hypnosis he discovered that he could ask subjects a dozen or so casual questions and make remarks that required an obvious "yes" answer so that positive momentum was gradually built up until they would finally also agree to enter a trance and then succeed in doing it.]

E: You also develop a yes set by saying, "You wouldn't do such and such," and they answer, "Yes, I wouldn't."

R: For a person who is negatively inclined you would emphasize all the things they wouldn't do.

E: And thereby evoke a "yes."

R: This is like mental judo. Actually it is a *utilization technique:* you are utilizing the person's characteristic attitudes.

E: That's right.

Posthypnotic Amnesia

And as a part of that experience

is forgetting that dream after you awaken.

An experience of forgetting in itself

is an experience

that is not alien to anybody.

(Pause)

E: The mention of "forgetting" tends to evoke posthypnotic amnesia without direct suggestion.

R: The verbal naming or description of a neuropsychological mechanism such as forgetting tends to evoke it. This seems to be a fundamental method of modern hypnosis.

Indirect Evocation of Personal Motivation and New Learning by Implication

Now with your background

you'll have many questions about many things.

You really don't know what those questions are.

You won't know what some of those questions are until they are half answered.

E: "You'll have many questions" implies: you will want to learn all you can and therefore you will participate fully.

R: You're evoking a learning set again.

E: And very forcefully.

R: By mentioning her "background" as a professional psychologist you evoke her professional pride and personal motivation.

E: That's right! And without boldly identifying what you're doing.

R: Yes. You did not say, "Because you are a psychologist you are going to be interested in this." You simply said, "with your background," and thereby evoked the best of her personal pride in herself as a professional.

Indirect Evocation of New Learning

And sometimes the answers

seem to be one thing

and turn out to be another.

R: The implication here is that new learning will take place: new answers to change the mental sets or mental habits that may be the source of a personal problem. You are structuring a learning set for therapeutic change.

E: Yes, new and different learnings for psychotherapeutic change. Without saying "Now I'm going to cram down your throat some new understanding."

Indirectly Discharging Resistance

The word April means a child—

it means a month.

(Pause)

But it can also mean April fool.

And so in your experiences be aware of the fact

that you really don't know where you are going to go,

but you are going to go.

R: Now you do a charming thing. You know that S has a young daughter named April, and you talk about her here. Why?

E: She can say, "Let's not drag my child into this." Now notice my emphasis on "April *fool."* All her rejection has to go on that one word.

R: I see. You've picked up her rejection with that one word "fool." You've crystallized and discharged her resistance.

E: Discharged it!

R: "April fool" discharged all the contumacy of the situation. So if resistance was building up you've discharged it here. You've discharged it indirectly with a pun.

E: Yes, and "April fool" also has pleasant associations. E: But this does imply that you *are* going someplace.

Engaging Motivation with Patient-Centered Experience

It all belongs to you.

E: If it all belongs to you, you want to take charge of it, don't you?

R: The burden is placed on her for carrying out the experience; she is to be the source of her own experience.

E: And because it belongs to her she *wants* it.

R: So you're again engaging her personal pride and motivating her.

E: That's right.

Hidden Directives by Implication

And it can be shared in any way that you decide.

E: You can't share a thing unless you've got it.

R: You imply there will be something to share. You again give the illusion of freedom when you say, "And it can be shared in any way you decide," but the hidden directives are (1) there will be something to share and (2) she will share it.

Evoking Courage and Self-Exploration

And one of the nicest things about hypnosis is

that in the trance state you can dare to look at

and think and see and feel things

that you wouldn't dare in the ordinary waking state.

E: I'm telling her that she has a lot more courage than she knows, and there will be more to become aware of than she knows.

R: Which of course is a scientific truism again: there is much more in our memory banks and associative structures than we are usually aware of in the normal conscious state. You use this truism here to evoke a set for self-exploration.

Truisms Evoking Mental Mechanisms: Protection and Flow from the Unconscious

And it is hard for any person to think that he can be afraid of his own thoughts.

But you can know that in this hypnotic state

you have all the protection of your own unconscious,

which has been protecting you in your dreams,

permitting you to dream what you wish,

when you wish,

and keeping that dream as long as your unconscious thought necessary,

or as long as your conscious mind thought would be desirable.

E: She has all the control.

R: She has all the protection she needs. She need not fear, her unconscious mind will take care of her. Is that right?

E: Right!

R: You're again verbally describing a scientific truism or natural mental mechanism that will by association tend to set that mechanism into operation. You earlier evoked "forgetting" in this way and now self-protection as a means of deeply reassuring her.

Depotentiating Consciousness

But your conscious mind will keep it only with the consent of your unconscious mind.

R: Is this again putting the conscious mind under the control or protection of the unconscious?

E: Yes. And it emphasizes that the unconscious can give to the conscious.

R: Again opening up a set for self-exploration, for things to flow into consciousness. I'm seeing this more and more: you're again utilizing a natural psychological mechanism, in this case the unconscious giving to the conscious, for therapeutic purposes here and now.

Facilitating Latent Potentials

Now the important achievement

for you

is to realize

that everybody

does not know

his capacities.

(Pause)

E: Who is important? She is! When you stop to think about it, nobody does know his capacities.

R: So again you're utilizing a scientific truism; in this case you're setting her up to enhance her latent potentials in any possible way.

E: That's right.

Allowing Time for Suggestions

And you have to discover these capacities in whatever slow way you wish.

E: In other words, you don't have to feel you must do it instantly.

R: This is an important principle in administering suggestions. When you don't know whether her unconscious is ready to carry out a particular suggestion, you allow her an indefinite time period to carry it out. Allowing indefinite time for suggestions is thus a fail-safe device. If the suggestion is not carried out immediately, it's not registered as a failure. The suggestion remains in a latent condition until it can be carried out.

[Erickson now tells a case history wherein a patient called him up 16 years after the termination of therapy to tell him of a new development in her life that was directly related to something he had told her in trance.]

Patient's Central Role

And one of the things I want you to discover is

you don't need to listen to me.

R: Again dismissing the conscious mind in favor of the unconscious.

E: And I'm also saying, "I'm not the important person, you are."

R: I see, again emphasizing the central role of the patient. The patient tends to think the therapist is the important person.

E: He isn't!

R: Patients keep pulling at the therapist for the cure, the magic, !. the change, rather than looking at themselves as the change agent. You are continually putting the responsibility for change back on the patient.

E: On to them always!

Words Evoking Mental Mechanisms

Your unconscious mind can listen

to me without

your knowledge

and also deal with something else at the same time.

(Pause)

E: A scientific truism, just as you step up and down from a curb without thinking about it.

R: You actually are evoking this psychological mechanism of *listening on an unconscious level* simply by describing it verbally. This is rather profound when you stop to think of it: you are using words to describe certain psychological mechanisms that you want to happen. Your verbal description evokes the psychological mechanism described.

E: It does.

Facilitating Change and Development

A person seeking therapy

comes in and tells you one story that is believed fully at the conscious level

and in nonverbal language can give you a story that is entirely different.

And the unconscious mind has had little opportunity

to give recognition to its own ways of understanding.

R: Again a therapeutic truism, but why are you presenting it?

E: I'm telling them, "You really don't know what's wrong with you." You tell them that so they won't think, "I know everything about my problem, my illness."

R: You're developing a learning set again for something new to come in. You're trying to open up their horizon, their experience. That's what the cure is going to be. You say the unconscious is going to have a new opportunity for expressing itself.

E: Too often the conscious behavior keeps you too busy so you deprive the unconscious of an opportunity to express itself. It's another scientific truism.

R: And so stated here it opens up the way for change and inner development.

Indirect Suggestions for Head Ideomotor Signaling

We learned to nod our heads for "yes" to shake our heads for "no." (Pause)

E: That is a fact and you pause to let them reflect on the factual nature of that statement. They have a chance to recognize that you are really speaking the truth.

R: This is actually your way of introducing her to ideomotor signaling. You don't tell her to nod and shake her head for "yes" and "no." You simply mention the possibility of nonverbal communication and let her own individuality decide how and when.

Facilitating Individuality

But that is not necessarily true of all people.

A cave people of the South Seas recently discovered have their own ways of nonverbal communication

where the cues are much slighter than we have.

E: Yes. Now each of us is an individual.

R: I see, that is the implication in describing these cave people with "their own ways" of communication. You are implying there is a place for her individuality, and you're evoking it thereby.

E: Yes, evoking it thereby.

R: Because that in fact is the problem with patients: many of their symptoms and so-called mental problems are due to a suppression of their individuality. The cure is to let that individuality come out and flower in all its particular genius.

E: That's right. That's what you need to do, and that is why they are seeing you.

Ideomotor Signaling the Acceptance of Suggestions

And your willingness to rely upon your unconscious mind

to do anything that can be of interest or value to you

is most important.

[S begins to nod her head very slowly.]

E: Emphasizing *she* is going to do something.

R: The fact that she does begin the *very slow, repetitive* head nodding characteristic of an autonomous ideomotor response may indicate that she is accepting your suggestion to rely on her unconscious mind.

Open-Ended Suggestions: Forgetting and Recall

Not only are you to learn positive things

but you need to learn negative things.

(Pause)

One of the negative things you need to learn is that of forgetting.

Consciously you can say to yourself,

"This I will remember."

To forget something seems very hard for some people.

And yet if they would look into their history,

they can forget as easily.

In teaching students in medical school

you tell them most impressively, "The examination will be held in such and such a room at such and such a time and in Building C

and will begin at 2:00."

And they will all listen with great interest,

and you turn to leave the classroom

and you will see the students lean toward each other

and say, What day?

What hour?

Building?

You know they heard it,

and they forgot it immediately.

(Pause)

R: Here you again talk about forgetting and give common examples of forgetting in everyday life to facilitate the possibility of evoking forgetting in the form of posthypnotic amnesia. She continues her very slow, slight, and repetitive head nodding throughout your words here. Does that mean she is accepting your ideas and will act upon them? In this case will she forget and experience an amnesia?

E: At some level she is responding with recognition or acceptance of what I am saying. But I don't know how she will act on it yet.

R: You can offer this loosely structured network of associations about forgetting, and it may or may not actually trip off forgetting mechanisms in her own mind. You do not impose suggestions or commands, you simply *offer* verbal associations that her individuality may or may not utilize. Trance does not ensure the acceptance of suggestions (Erickson and Rossi, 1975); it is simply a modality wherein the patient's mental processes have an opportunity to interact in a more spontaneous and autonomous manner with the therapist. At this early stage of trance training you are simply exploring how her individuality will respond to suggestions you offer in an open-ended manner.

The Apposition of Opposites

That is a facility in behaving that serves many good purposes.

And you should enjoy learning to forget not only ideas

but nonverbal performances.

Purposely forgetting that you know a certain name

doing as you did as a child

when you decided you liked a different name

and perhaps for a half day you entertained that your name was Darlene

or Ann Margaret

[S appears to renew her slow head nodding at this point in apparent recognition or acceptance of what is being said.]

E: This is a very common game among children and it reminds her of a forgotten game.

R: Giving her yet another example of a forgotten experience. This is a way of proving you can forget.

E: But they will *recall* the forgotten memory of their experience with the game.

R: They will do the opposite of forgetting when they recall; they then prove they have forgotten.

E: And at the same time they are verifying the validity of what I have been saying.

R: And it is possible you may have elicited a forgotten memory. So you have done two things that are the opposite of one another. You have facilitated forgetting and you have facilitated recall. You are juxtaposing mental mechanisms that are usually very delicately balanced: forgetting and recall. They are delicately balanced in our neurophysiology, and you delicately balance them here for therapeutic purposes. We will call this the apposition of opposites wherein you attempt to balance opponent mental processes. This careful balance is another means by which you give her individuality a chance to express itself.

Amnesia and Dissociation: Losing Abilities

It's a very remarkable thing to discover

that you can lose an arm,

a leg,

an entire moment.

You can forget where you are.

(Pause)

R: Another set of examples of how forgetting can take place by dissociation.

E: And everybody has that experience.

R: Yes. You would never take a chance and say something that everyone doesn't always have. You speak in truisms for complete acceptance. People have to accept what you say because it is all true. You then pause to let them assimilate your message.

E: And I'm evoking memories

Conscious and Unconscious

Now there are some different ways in which the mind can function

in which the unconscious can join with the conscious,

many different ways in which the unconscious can avoid the conscious mind

without the conscious mind knowing that it is

just received a gift.

(Pause)

R: A series of truisms about the relations between conscious and unconscious here. You continually use these truisms to (1) establish that you are a reliable source of the truth and (2) to evoke certain mental mechanisms and modes of functioning. When these truisms do trip off the described psychological mechanisms (for example, the

unconscious releasing a forgotten memory to the conscious), you also thereby establish the validity and value of trance in a very safe way. In therapeutic work you never use direct challenges to prove the trance.

E: That's right.

R: This is a much more effective and interesting way of establishing the validity of trance, and you are less likely to arouse resistance.

Facilitating Latent Potentials by Implication

The very complexity of mental functioning

you can go into a trance to find out

a whole lot of things that you can do.

And they are so many more than you dreamed of.

(Pause)

E: This implies: *you* do have an important purpose in going into a trance. It is not what I can do but what *you,* the patient, can do. You emphasize all the things the patient can do.

R: You are using implication to initiate a process of inner exploration that may facilitate the recognition of potentials she did not know she had.

Evoking Early Experience

You can dream of yourself as a small child,

wondering who that child is.

(Pause)

R: This may be evoking early memories or an age regression, but with the safe distancing device of "wondering who that child is." You do not precipitate the patient into an actual experience of reliving the past since that might be traumatic at this early stage of therapy.

E: You do not elicit the common response, "But I can't be a child." But they *can* wonder who the child is. While they wonder they can say, "I can be that child."

R: You speak of it in the context of "You can dream of yourself as a small child." Is that actually evoking mechanisms of dream formation?

E: Yes, and using them in another way.

R: So again you are utilizing a natural neuropsychological mechanism by evoking it verbally.

E: And when you say, "You *can* dream," it implies you can also do it any other way you want to.

R: You did not say, "You will dream of yourself." That would be limiting it to dreams only. You say "You *can* dream" and imply, "But you could fantasize it, talk to yourself about it, or whatever."

E: You can do it any way you wish, but you will do it.

Ratifying Age Regression

And you can watch that child grow older,

week by week,

month by month,

year by year.

Until finally you are able to recognize who that child is

who is growing up.

[S's head appears to nod very slightly.]

R: You are now ratifying the regression by having her watch herself grow up.

E: Yes, if she watches herself grow up, that implies and ratifies the fact that she experienced herself as a child.

Facilitating Abilities via Dissociation

Every person has abilities

not known to the self,

abilities discredited by the self.

If there is an ability that the unconscious wants to disown,

it can examine that ability,

examine it very fully, very completely, and when it desires,

obliterate that ability

but doing so with an adequate understanding of the fact that an obliteration has been effected.

[Here Erickson spends about 15 minutes giving a fairly complex clinical example of how the unconscious can obliterate a memory.]

E: Everyone does this; a truism again.

R: By discussing this disowning of abilities you are actually setting the stage for facilitating processes of dissociation?

E: You only obliterate when there is that ability. By actively illustrating it, you prove it is there. Since it is there we will use it.

R: You are evoking the obliteration mechanism in the unconscious?

E: Yes, but only temporarily to let her know it is there.

R: Oh, are you implying that the unconscious has obliterated a lot of things but it can also bring them forward when it wants to ?

E: Yes.

R: So you are setting her up for possible memory recall of anything the unconscious has obliterated.

E: That's right. Only she does not know what you are doing. R: You are speaking directly to her unconscious here.

E: And using her own growth and experience, that's all your talking about.

Implication Even in Direct Suggestion

Now I am trying to map out some things you can learn.

R: You make such a direct statement here. I'm shocked.

E: "I am trying," and since you feel kindly toward me this implies: you will help me.

R: Indirectly placing the essential burden on her again. So even when you make a direct statement, you may be implying other things, and the really important suggestion is contained in that implication.

Hallucination Training

Now in hallucinating visually

sometimes you want to start it by keeping your eyes closed

and knowing they are closed.

(Pause)

There is no set time

for you to learn

to remain into trances with your eyes wide open.

(Pause)

E: Here she is beginning to realize that a hallucination is not just a psychotic thing. She can see it in her mind's eye.

R: You are redefining hallucination as something that can be seen in the mind's eye with one's eyes closed. You're making it a safe and easy thing they can do.

E: It may look like a challenge, but it isn't one. You may "start it by keeping your eyes closed" implies that it doesn't make a damn bit of difference whether your eyes are open or shut.

R: Then you throw in the safety phrase, "There is no set time." It can happen now or next week.

E: In the final pause you exude confidence.

Trance as Common Experience

You have already had some experiences of being in a trance with your eyes wide open.

(Pause)

E: Anyone absentmindedly looking out the window during a lecture is experiencing trance with eyes wide open. You are oblivious to the external lecture and your surroundings as you tune into inner realities. Everyone has had that experience.

R: You are defining trance in this way: not paying attention to your immediate surroundings, being off someplace else mentally.

E: Trance is a common experience. A football fan watching a game on TV is awake to the game but is not awake to his body sitting in the chair or his wife calling him to dinner.

Awakening as a Creative Option

Now, we'll shift over to another part of your learning.

You can awaken from the trance at will,

awaken by counting back from 20 to 1.

R: You seemed fairly tentative as you gave these awakening instructions. You thus gave her a creative option to awaken at this time. But if she was absorbed in interesting and important work at that moment, there was an implication that she could continue for a while yet. This ensures that awakening will be a pleasant experience rather than a rude interruption.

The Double Dissociation Double Bind: Dissociation Training

You can as a person awaken,

but you do not need to awaken as a body.

(Pause)

R: With the following sentence this forms a double dissociation double bind.

E: Yes. You are making it possible for the subject to comprehend the idea of a dissociation between the mind and the body.

Possibilities of Posthypnotic Suggestion

You can waken when your body awakes but without a recognition of your body.

(Pause)

E: Here I'm giving the possibility of posthypnotic suggestion.

R: Now this is a very important aspect of your technique. You give possibilities for posthypnotic behavior and you wonder yourself which of these will be fulfilled. You have no way of knowing which will be realized, but when they are, you can take credit for them.

E: You take credit only when you are given credit.

R: You just smile when they fulfill a posthypnotic suggestion, and they know you've had a hand in it, which you have.

E: But not to the extent that they think.

R: So throughout the induction you may give many possibilities of posthypnotic behavior but not in a bold way, as 1 once did in my early work when I told a subject that he would "casually touch the ashtray after the trance was terminated." When he awakened, he said he remembered my posthypnotic suggestion but he "did not feel like carrying it out." He came back the next session saying he had been preoccupied all week with why he had not touched the ashtray. Obviously he was influenced by the suggestion, but I presented it so directly that it aroused resistance and actually precipitated a conflict between touching and not touching and the question "why" that bothered him all week. It may be dramatic for the purposes of the stage hypnotist to select subjects who will "obey direct commands," but the hypnotherapist who must work with all patients must carefully study what natural tendencies the individual patient has that can be funneled into therapeutically useful posthypnotic behaviors.

Exploring Identity Formation

Our understanding of ourselves is very complicated.

A child first learns,

I love me,

(Pause)

and then proceeds one day,

I love my brother, my father, my sister, but what the child

is saying—

I love the me in you.

(Pause)

And that's all the child does love.

The me in you.

(Pause)

As the child progresses,

(Pause)

the child now learns

to love your beauty, your grace, intelligence,

but that is his perception of the you.

(Pause)

R: Here the focus is on the person's identity and how it developed?

E: You're evoking, "I am me, I am doing this, I'm going to keep on doing this."

R: You're focusing on the work to be done by her in trance? E: Yes.

R: By this general description of identity formation you are offering a series of truisms that may help keep her focused on her own individual inner work. You also may be helping her explore important facets of the development of her own identity.

Positive Motivation and Reward in Trance: Facilitating the Growth of Identity

In the final stage it is learning in your happiness

I will find my happiness,

(Pause)

and that is the separation of the identity of one person

from the identity of the other.

E: "In your happiness I will find my happiness." Everyone wants to give and find happiness. Their happiness right now in the trance will be some accomplishment.

R: I see, you're actually motivating her to accomplish something for which she will be happy. You do everything you can to create an atmosphere of positive motivation and reward in trance experience. By interspersing this positive feeling within the general context of exploring her identity, you also may be associating a reward with the development and separation of personal identity. You are indirectly facilitating the growth of her identity.

Spontaneous Awakening in a Give-and-Take Relationship

[Subject spontaneously opens her eyes and reorients to her body.]

R: You did not know she was going to open her eyes at this point?

E: No.

R: Yet you gave her the option earlier of counting from 20 to 1 to awaken. Your open-ended manner gave her the creative option of awakening when she felt ready to. You structured an awakening, yet you gave her the freedom of when even if it was inconvenient for you.

E: That's right. You give them the freedom to awaken at the wrong time for you. Then they are in the mood to continue for you.

R: There is a give and take in your relationship with patients.

Making Trance Safe: Separating Conscious from Unconscious

E: Now, what's happened to you?

S: Me?

E: Yes, what happened to you?

(Pause)

You wait and don't discuss it because what you're going to do is separate your understandings and clarify those and individualize them.

(Pause)

At the present time you have a partially conscious and partially unconscious understanding, and we don't know where to place the emphasis.

(Pause)

R: Now that she's awakened, we enter that important period of ratifying the trance. Her question, "Me?" implies she is not completely oriented yet. It takes most people a moment or two to awaken from trance. That is another indicator of a genuine trance experience.

E: You will "separate your understandings" implies: you have got understandings of two varieties, conscious and unconscious.

R: And you are going to do more work on them as time goes on. E: That's right.

Structuring Frames of Reference for Clinical Inquiry

There is one thing in therapy that is so important.

(Pause)

When you touch upon another person's emotions,

(Pause)

you always touch tender places, and they don't know where those tender places are.

(Pause)

You have had your first experience of a quick withdrawal.

(Pause)

Maybe you were trying to find why you were withdrawing

or what you were withdrawing from.

S: I didn't know I was.

R: You say that you didn't know you were withdrawing front hypnosis?

S: Yes.

R: Here you soften any possible negative implications of her awakening by generalizing about tender places and emotions in therapy. You provide a frame of reference for talking about tender emotions. You avoid direct questioning about such tender spots since that tends to arouse resistance and at best only elicits an answer that is hedged by all sorts of conscious inhibitions and limitations. By simply providing her with a gentle frame of reference, on the other hand, you're giving her an opportunity to say something that's important if she wants to; you're providing her with an opportunity for growth that is automatically appropriate for whatever level she is at, since she can choose to say whatever she wants within the frame you've provided.

E: I'm asking for what she may be thinking without being blunt and putting her on the spot.

R: Yes, your statement about withdrawing provides a frame that may enable her to say something about whatever she might have experienced as negative. Her statement that she did not know she was withdrawing indicates she feels her awakening was a natural and satisfying termination rather than an abrupt withdrawal or escape from something unpleasant in trance.

Distraction to Maintain Separation Between Trance and Waking Patterns

E: By the way, what time do you think it is?

S: I thought it was about 4:30.

E: Does it feel a half-hour has passed?

R: Were you trying to distract us by throwing in that question?

E: Yes. It was a distraction. You don't want too much self-analysis immediately. A person freshly out of the trance is still lingering close to it, and unconscious knowledge is easily available. You don't know if that should be used yet. So you distract them.

R: You want to make a definite separation between trance and waking behavior. You don't want the in-between state that blurs the distinction.

E: You do not want to blur that distinction.

Making Trance Safe

S: Well, it's kind of hard to judge because I was flashing back to when I was 16. I think the first time I went ahead in time to about 40 years of age and we were visiting April's children and there were four kids that were climbing around a banyan tree.

R: You went into the future?

S: Yes, I lived in the future.

Well, I have thought about it, but I dreamed about it too.

E: Where was April when you were thinking about her and her children?

S: Where was she? I don't know where she was; it seemed as if she was off doing something. She was going to be there soon.

E: Where was that place? What was that place?

S: She just had these girls playing around a banyan tree. Just some time in the future.

E: The implication of this, of course, is that S did want to have four children herself (this was later verified as true), and she is now projecting it into a fantasy of the future when she can play with her daughter April's four children. But she does not know I know this, she does not know it herself. Her unconscious knows a lot she does not know. In not promptly analyzing this and telling her about it, I've also let her know it is safe to fantasize and project herself in this way.

R: Yes. You've made the trance experience safe for her. You did not learn anything from her trance that is going to frighten or traumatize her life. You make the trance a safe and pleasant experience.

E: And she can trust me.

R: So we go on talking about the trance in an intellectual way that's safe.

(Erickson gives an example of a patient who once slapped him across the face because she was not yet ready to talk consciously about trance events she was still partly associated with in the first moments of awakening.)

Subjective Experience of Trance: First Step to Visual Hallucinations

E: Do you know what you just said?

S: No.

E: What is the approach some people make toward active hallucination?

S: A while before, you said something about not having to pay attention to your voice, but your voice had already gotten pretty distant because 1 felt pretty relaxed. But you mentioned something about hallucinations. Just about then I saw a great heart, and it had different layers. I don't know if it had something to do with that (referring to the irregular green-tinted glass she had used for an eye fixation point.) Well, when I first looked at it, it looked like seaweed, but I was imagining I was just swimming along in the ocean.

(Pause)

I guess I'm just skipping around now.

E: Yes. To get a real hallucination is an unreality, and what is more unreal than April's four children?

S: Well, it was like a dream in that respect.

They were cute little girls climbing through the tree.

R: Here she gives an excellent description of some of the subjective experiences of trance. Especially noteworthy is her comment to the effect that when she was relaxed, your voice already became "pretty distant." In relaxation, then, we automatically diminish the subjective experience of all the sensory modalities.

This is the basis of using relaxation and hypnosis for pain and similar problems.

Her internal imagery with eyes closed was a symbolic approach toward experiencing visual hallucinations with eyes open. This was her first response to your earlier suggestions about hallucinating visually.

E: And a very effective one. She is very sophisticated with terminology—more so than she realized—and she betrayed that fact by seeing April's children.

R: Seeing April's children is in the visual modality, the modality of visual hallucinations.

E: Yes.

Reinforcing the First Stages of Visual Hallucinations

R: You saw all that? So this was your first approach to hallucinatory experience.

E: And very, very real approach, and the approach of someone who is sophisticated without knowing that she is sophisticated.

R: And without knowing that she is approaching hallucinatory behavior.

E: At a completely sophisticated level.

R: Let me ask what you mean by "sophisticated."

E: She knows what hallucination is. She accepted my abstract and sophisticated concept "hallucination" and used it to see an unreality projected into the future.

R: I can see we were both very quick to reinforce her first step toward hallucinations with very supportive remarks here. It is also fascinating to see how she spontaneously oriented herself into the future without any suggestion from you. I suppose this is how most hypnotic phenomena were discovered. Someone does something interesting spontaneously, and then an alert investigator tries to evoke it in others.

Trance Characteristics

S: Now, I'm trying to think better. It was kind of hard to think, flashing around in that state.

R: In the trance it's harder to think?

S: Yes

(Pause)

S: Another thing flashed into my mind when Dr. Erickson mentioned going back and assuming another identity. I used the name Amy for a while in high school because we were all using different names. When you mentioned Ann Margaret, that Amy identity flashed in my mind.

(S continues to recount other memories of her teen years that she touched upon in trance.)

E: How long had it been since you thought about Amy?

S: About 20 years. That's funny. Oh well, I think you said something about awakening by counting back from 20 or something, and I did it but then I didn't know if I was right in waking up.

R: Such spontaneous comments as these about how hard it is to think in trance suggest that trance (at least as she experienced it) is an altered state characterized by less control over cognitive processes. Trance is a giving up of controls over internal processes as well as external behavior. Thus processes of cognition, imagery, and emotion are experienced as flowing by themselves in an involuntary manner. Awakening is a process of reasserting control over thinking (as she expresses so well here) and behavior (body reorientation).

Movements and Identity

E: You were giving signs that I had hit on a definition of identity.

R: What were the signs?

E: Movements in her muscles here and there, especially in the thighs.

R: I see, that's why you were watching her hands resting on her thighs. You were watching those muscles. I also noticed her fingers were moving at a certain point. I'd like to have you say more about this, Dr. Erickson. About the signs you were picking up on her.

R: You mentioned that when a patient's identity is touched, they show certain body movements. How would you suggest a beginning hypnotherapist train himself to deal with this? Would you wake up a patient when he begins showing such movements and ask about them or simply ask while the patient is in trance?

E: When you continue with one subject long enough, they will gradually tell you everything without your even asking.

R: Sensing that S was caught up in her identity by observing the movements in her muscles and fingers—did that motivate you to suggest termination by counting backward from 20 to 1?

E: I knew she was going to wake up in a direct relationship to the identification with maturity.

Spontaneous Finger Signaling

E: Usually a patient in a trance remains immobile. When you see her move, you immediately try to connect the movement with the words you have been using.

R: When you see her finger move, you try to connect it with what you have been saying?

E: Yes.

R: A more naive hypnotherapist, a beginner like myself, might think, "Oh she is just waking up." But her awakening has psychodynamic meaning. You saw those twitches starting to take place and you understood this as a show of recognition or identity with what you were saying.

E: Yes.

R: After this session S casually mentioned to me that she had recently witnessed a demonstration of finger signaling. She felt that even though you did *not* suggest the possibility of finger signaling to her, the finger movements I noticed were her initial efforts at finger signaling. She wanted to experience finger signaling because she was fascinated with it when she had previously witnessed it. She therefore used this trance as an opportunity to experience something she was interested in without even telling you about it. She said she was surprised and delighted when she noticed that her fingers moved all by themselves. It is a curious dissociation: she wanted to experience finger signaling and yet she did it in an entirely spontaneous and autonomous manner. Of course, her finger signaling could also be a generalization from your earlier suggestions for head signaling.

Open-Ended Suggestions:
Unconscious Selection of Hypnotic Experience

S: What did they mean, if I wasn't aware of them?

E: You were having flashes of identity of yourself as a child, maybe flashes of your identity as you grew, flashes of your identity as an adolescent, and then a very strong identification of yourself as a woman.

R: So in this presentation, Dr. Erickson, you allowed her many possibilities. You used a buckshot approach which allowed her unconscious to select just what it wanted to experience. You offered suggestions in an open-ended manner.

E: Yes, you phrase your suggestions in such a manner that the patient's own unconscious can select just what experience is most appropriate at that time.

THE "YES SET"

The "yes set" is another basic hypnotic form for coping with the limitations of a patient's rigid and negativistic conscious attitudes. Much initial effort in every trance induction is to evoke a set or framework of associations that will facilitate the work that is to be accomplished. In the first session, for example, he evoked the "early learning set" as an analog of the new learning situation that hypnosis represented for Dr. S. Just as she successfully learned her ABC's, so she would successfully learn to experience trance. Thus, the early learning set could itself be understood as a "yes set" serving as a framework to orient her to the trance work at hand.

One of Erickson's favorite anecdotes is about a beginning student who discovered the usefulness of the "yes set" in hypnotic induction. The student found himself confronted by a hostile subject who adamantly refused to accept the possibility that he could experience trance. The student, acting on a creative hunch, then simply proceeded to ask the resistant subject a series of 20 or 30 questions all of which would elicit an obvious answer of "yes." All sorts of simple and *boring* questions such as the following could be used.

Are you living at x address?
Do you work at x?
Is today Tuesday?
Is it 10:00 A.M.?
Are you seated in that chair?

Without realizing it the subject develops a "yes set" and also becomes a bit bored with the situation. At this point the student finally asked again if the subject would like to experience trance. The subject then acquiesced simply because of the "yes set" and his desire to escape the dull circumstance of simply saying "yes" to obvious questions.

Exercises with the "Yes Set"

1. We believe the "yes set" is closely related to the concept of rapport, which has traditionally been regarded as a basic feature of the therapist-patient relationship in hypnosis. It is the essence of Erickson's approach to the "resistant" patient who is usually unable to control his own antagonistic, defensive, and self-defeating behavior. Erickson (1964) illustrates as follows:

Perhaps this can be illustrated by the somewhat extreme example of a new patient whose opening statement as he entered the office characterized all psychiatrists as being best described by a commonly used vulgarity. The immediate reply was made, "You undoubtedly have a damn good reason for saying *that and even more." The* italicized words were not recognized by the patient as a direct intentional suggestion to be more communicative, but they were most effective. With much profanity and obscenity, with bitterness and resentment, and with contempt and hostility he related his

unfortunate, unsuccessful, repeated, and often prolonged futile efforts to secure psychotherapy. When he paused, the simple comment was made casually, "Well, you must have had a hell of a good reason to seek therapy from me." (This was a definition of his visit unrecognized by him.)

Plan how you can learn to recognize, share, and utilize a patient's own words and frames of reference to facilitate the transformation of "seemingly uncooperative forms of behavior into good rapport, a feeling of being understood, and an attitude of hopeful expectancy of successfully achieving the goals being sought."

PSYCHOLOGICAL IMPLICATION

An understanding of how Erickson uses implication will provide us with the clearest model of his indirect approach to hypnotic suggestion. Since his use of "implication" may involve something more than the typical dictionary definition of the term, we will assume that he may be developing a special form of "psychological implication" in his work. For Erickson, psychological implication is a key that automatically turns the tumblers of a patient's associative processes into predictable patterns without awareness of how it happened. The implied thought or response seems to come up autonomously within patients, as if it were their own inner response rather than a suggestion initiated by the therapist. Psychological implication is thus a way of structuring and directing patients' associative processes when they cannot do it for themselves. The therapeutic use of this approach is obvious. If patients have problems because of the limitations of their ability to utilize their own resources-, then implications are a way of bypassing these limitations.

If you sit down, then you can go into trance.

Any implication stated in the logical "if. . .then" form can be a useful way of structuring a suggestion. The introductory "if phrase states a condition that is acceptable or easily accomplished by the patient so that a "yes set" is created for the suggestion that follows in the concluding "then" phrase.

Obviously, you are not going into a trance, now!

"Now" lasts only for a short while; the implication is that you will go into a trance as soon as "now" is over.

Certainly your arm won't be numb before I count to five.

Implies it will be numb after a count of five.

In every psychological implication there is a direction initially structured by the therapist and a response created by the patient. In the above we are initially structuring the implications that will direct the patient's associations and behavior in predictable directions. Exactly when the patient will go into trance or how numbness will be created, however, are responses mediated on an unconscious level by the patient. Consider the following examples:

Before you go into trance, you ought to be comfortable.

The most obvious implication is that one will go into trance after one is comfortable. The very process of getting comfortable, however, also evokes many unconscious adjustments of relaxation and not doing that are also important for initiating trance experience.

The very complexity of mental functioning,

A truism.

you go into a trance to find out

A phrase which implies that the patient does have an important purpose in going into a trance.

a whole lot of things you can do.

This implies that it is not what the therapist can do but what the patient can do that is important.

And there are so many more than you dreamed of. (pause)

The pause implies that the patient's unconscious may make a search to find some of these individual things she was previously unaware of.

It is important in formulating psychological implications to realize that the therapist only provides a stimulus; the hypnotic aspect of psychological implications is created on an unconscious level by the listener. The most effective aspect of any suggestion is that which stirs the listener's own associations and mental processes into automatic action. It is this autonomous activity of the listener's own associations and mental processes that creates hypnotic experience.

There are, to be sure, crude and mostly ineffective uses of implication in everyday life, where the speaker in a very obvious manner attempts to cast negative implications or aspersions on the listener. In such crude usage the implication is obviously created entirely by the speaker. In our use of psychological implication, however, we mean something quite different. In the psychological climate of the therapeutic encounter the patient is understood to be the center of focus. Every psychological truth is consciously or unconsciously received by the patient for its possible application to himself. Psychological implication thus becomes a valuable indirect approach for evoking and utilizing a patient's own associations to deal with his own problem.

This was well illustrated when a colleague referred a rebellious teenager to Erickson. He listened quietly to the lad's story and then initiated an important therapeutic development with one simple statement.

I don't know how your behavior will change.

The rebellious teenager was in no mood to accept advice from a doctor, and, in truth, Erickson really did not know how his behavior was going to change. By openly admitting that he did not know, Erickson disarmed the lad's resistance so he could momentarily experience an *acceptance set.* Erickson then managed to insert one implication in that moment of acceptance: "Your behavior will change." The boy was now left with the idea of change; his own associations and life experience would have to create exactly how that change was going to take place.

Exercises in Psychological Implication

1. Exercises in implication and clinical inference were Erickson's first approach in training the junior authors. He dragged out old protocols, some of them 25 years old or more, and gave the junior authors the exercise of reading the first page or two and then, by implication and inference, predict what was to follow. Another set of exercises was to study the first sketch of a character by Dostoevski or Thomas Mann and by implication infer what the character's fate would be in the novel. For a period of his life Erickson enjoyed whodunit fiction for the same purpose. Study recordings of your own therapy sessions, particularly initial interviews, and explore the possible implications of each of the patient's remarks. Then study the implications of your own. How many are actually therapeutic?

2. Study recordings of hypnotic inductions, particularly your own. Learn to recognize the implications that are present in your voice dynamics (such as intonations and pauses) as well as the content of your words.

3. Carefully construct sentences that (a) state a general psychological truth that (b) by implication initiates an inner search that will (c) evoke and mobilize the listener's own memories, associations, ideomotor and ideosensory responses, and so on.

4. Carefully write out hypnotic inductions formulating a series of psychological implications that can facilitate trance and each of the classical hypnotic phenomena.

THERAPEUTIC BINDS AND DOUBLE BINDS

The concept of the double bind has been used in many ways. We use the terms "bind" and "double bind" *in a very special and limited sense* to describe forms of suggestion that offer patients the possibility of structuring their behavior in a therapeutic direction. A *bind* offers a free choice of two or more comparable alternatives—that is, whichever choice is made leads behavior in a desired direction. Therapeutic binds are tactful presentations of the possible alternate forms of constructive behavior that are available to the patient in a given situation. The patient is given free, voluntary choice between them; the patient usually feels bound, however, to accept one alternative.

Double binds, by contrast, offer possibilities of behavior that are outside the patient's usual range of conscious choice and control. Since the original formulation of the double bind (Bateson, Jackson, Haley, and Weakland, 1956) as a hypothesis about the nature and etiology of communication in schizophrenia, a number of authors have sought to utilize the concept of the double bind to understand and facilitate psychotherapy and hypnosis (Haley, 1963; Watzlawick et al., 1967, 1974; Erickson and Rossi, 1975). Since we use the term in a very special and limited sense, we will present only an outline of how we conceptualize the double bind for an understanding of therapeutic trance and hypnotic suggestion.

The double bind arises out of the possibility of communicating on more than one level. We can (1) say something and (2) simultaneously comment on what we are saying. We may describe our primary message (1) as being on an object level of communication while the comment (2) is on a higher level of abstraction, which is usually called a secondary or metalevel of communication (a metacommunication). A peculiar situation arises when what is stated in a primary communication is restructured or cast into another frame of reference in the metacommunication. In requesting an ideomotor response such as hand levitation, for example, we (1) ask patients to let their hand lift but (2) to experience it as lifting in an involuntary manner. In requesting an ideosensory response we may (1) ask patients to experience a hallucinatory sensation of warmth, but (2) it is usually understood that such an experience is outside patients' normal range of self-control. Therefore, patients must allow the warmth to develop on another, more involuntary level. We have many ways of saying or implying to patients that (1) something will happen, but (2) you won't do it with conscious intent, your unconscious will do it. We call this the conscious-unconscious double bind: since consciousness cannot do it, the unconscious must do it on an involuntary level. Conscious intentionality and one's usual mental sets are placed in a bind that tends to depotentiate their activity; unconscious potentials now have an opportunity to intrude. The conscious-unconscious double bind is the essential basis of many of the therapeutic double binds discussed in the following sections.

In actual practice the metacommunication that comments on the primary message, may take place without words: one may comment with a doubting tone of voice, a gesture or body movement, subtle social cues and contexts. Hidden implications or unconscious assumptions may also function as a metacommunication binding or qualifying what is said on the ordinary conversational level. Because of this the patient is usually not aware that conflicting messages are being received. The conflict is frequently enough to disrupt the patient's usual modes of functioning, however, so that more unconscious and involuntary processes are activated.

Ideally, our therapeutic double binds are mild quandaries that provide the patient with an opportunity for growth. These quandries are indirect hypnotic forms insofar as they tend to block or disrupt the patient's habitual attitudes and frames of reference so that choice is not easily made on a conscious, voluntary level. In this sense a double bind may be operative

whenever one's usual frames of reference cannot cope and one is forced to another level of functioning. Bateson (1975) has commented that this other level can be "a higher level of abstraction which may be more wise, more psychotic, more humorous, more religious, etc." We simply add that this other level can also be more autonomous or involuntary in its functioning; that is, outside the person's usual range of self-direction and -control. Thus we find that the therapeutic double bind can lead one to experience those altered states we characterize as trance so that previously unrealized potentials may become manifest.

In actual practice there is an infinite range of situations that may or may not function as binds or double binds. What is or is not a bind or double bind will depend very much on how it is received by the listener. What is a bind or double bind for one person may not be one for another. In the following sections, therefore, we will describe a number of formulations that may or many not lead a particular patient to experience a bind or double bind. These formulations are "approaches" to hypnotic experience; they cannot be regarded as techniques that invariably produce the same response in everyone. Humans are too complex and individual differences are simply too great to expect that the same words or situation will produce the same effect in everyone. Well-trained hypnotherapists have available many possible approaches to hypnotic experience. They offer them one after another to the patient and carefully evaluate which actually lead to the desired result. In clinical practice we can only determine what was or was not a therapeutic bind or double bind in retrospect by studying the patient's response. The following formulations, therefore, offer only the possibility of therapeutic binds or double binds that may structure desired behavior.

I. The Bind and Double Bind Question

Binds are easily formed by questions that give the subject a "free choice" among comparable alternatives. Any choice, however, facilitates an approach toward a desired response. To facilitate the acceptance of the trance situation a great number of possibilities exist, such as the following:

Would you like to experience a light, medium, or deep trance?

Would you like to go into trance sitting up or lying down?

Would you like to have your hands on your thighs or on the arms of the chair when you go into trance?

We could designate these questions as binds because while they do structure a trance situation, they can easily be answered by most people with their usual conscious sets. For some people, however, the second example could function as a double bind if it is found that they do, in fact, go into a trance when they sit or lie down in response to the question.

The following questions, by contrast, are more typically double binds because they cannot be answered with one's usual conscious sets. One must usually relax and allow more autonomous or unconscious functions to fulfill them. Such double bind questions are of particular interest for facilitating Erickson's experiential approach to hypnotic phenomena. By turning attention to one's subjective experience, one is focused inward in a manner that can lead easily to an experience of trance and hypnotic phenomena. This question approach is also particularly suitable for those subjects who respond to the initial phase of trance induction with hyperalertness, anxiety, or tension. The question allows them to utilize their conscious focus to facilitate the recognition of the suggested phenomena. The question double bind is thus very useful for "resistant" subjects, who need to use their consciousness to maintain some control in the hypnotic situation. Consider these examples:

Will your right hand or your left begin to feel light first? Or will they both feel that lightness at the same time?

Will your right hand move or lift or shift to the side or press down first? Or will it be your left hand?

Do you begin to experience a numbness in the fingers or the back of the hand first?

What part of your body begins to feel most comfortable (warm, cool, heavy, etc.)?

These questions may function as double binds because a hypnotic suggestion in the form of an ideomotor or ideosensory response is being facilitated no matter which alternative is experienced. When naive subjects experience such phenomena for the first time, they are usually surprised and a bit delighted. Such phenomena are experiential proof that they can learn to develop latent potentials and altered modes of functioning for further therapeutic work.

2. The Time Bind and Double Bind

Time is an excellent dimension for formulating binding questions and situations.

Do you want to enter trance now or in a few minutes?

Would you like to go into trance quickly or slowly?

Will you be ready to get over that habit this week or the next?

These questions can be answered with one's usual frames of reference and may therefore be classified as binds that simply focus attention in the direction of a desired response. Whatever the patient's answer, however, they are being bound to make the therapeutic response—either now or later. With some subjects the first two questions may actually evoke the initial experiences of trance; for them the context of the hypnotherapeutic situation and the therapist's attitude of expectation that they will go into trance may function as metacommunications that activate autonomous processes leading them into trance experience.

Double binds utilizing time to evoke responses on a more autonomous level may be structured as follows:

Please let me know when that feeling of warmth develops in your hand. Is that anesthesia proceeding quickly or slowly?

Take all the time you need to really learn how to experience that (any ideomotor or ideosensory response) in that special trance time where every moment in trance is equivalent to hours, days, or even weeks of regular time.

All of these questions and situations utilizing time contain a strong psychological implication that the desired response will take place. Most hypnotic responses take time. In trance subjects usually experience "psychomotor retardation." There is a lag between the time when a suggestion is given and when the subject is finally able to carry it out. The time bind capitalizes on this time lag and makes it an integral part of the hypnotic response.

A charming example of the possibility of a therapeutic double bind utilizing time was offered to a six-year-old boy by Erickson.

I know your father and mother have been asking you, Jimmy, to quit biting your nails. They don't seem to know that you're just a six-year-old boy. And they don't seem to know that you will naturally quit biting your nails just before you're seven

years old. And they really don't know that! So when they tell you to stop biting your nails, just ignore them!

Of course, Jimmy did not know that Erickson knew that he would be seven in a few months. Erickson's words, uttered with sincere conviction and in a confidential tone implying that he was taking Jimmy into secret confidence, were enough to double bind Jimmy into giving up nail biting within two months in a way that the boy could not consciously understand. He could not understand, for example, how his pleasure in being permitted to ignore his parent's irritating demands that he stop biting his nails actually reinforced the double bind that activated his own internal resources to create a way of giving up nail biting on his own. As it turned out, Jimmy was later able to brag that he quit a whole month before he was seven years old.

3. The Conscious-Unconscious Double Bind

Erickson frequently gives a preinduction talk about the differences between the functioning of the conscious mind and the unconscious mind. This prepares the patient for double binds that rest upon the fact that we cannot consciously control our unconscious. The conscious-unconscious double bind blocks the patient's usual voluntary modes of behavior so that responses must be mediated on a more autonomous or unconscious level. Any response to the following situations, for example, requires that the subject experience trance.

If your unconscious wants you to enter trance, your right hand will lift. Otherwise your left hand will lift.

You don't even have to listen to me because your unconscious is here and can hear what it needs to to respond in just the right way.

And it really doesn't matter what your conscious mind does because your unconscious automatically will do just what it needs to in order to achieve that anesthesia [age regression, catalepsy, etc.].

You've said that your conscious mind is uncertain and confused. And that's because the conscious mind does forget. And yet we know the unconscious does have access to so many memories and images and experiences that it can make available to the conscious mind so you can solve that problem. And when will the unconscious make all those valuable learnings available to your conscious mind? Will it be in a dream? During the day? Will it come quickly or slowly? Today? Tomorrow?

In this series of double binds the therapist is using an open-ended approach. The therapist gives a number of truisms about psychological functioning, any one of which will help to solve the patient's problem. The value of this open-ended approach is that it gives the patient's unconscious the freedom to work in whatever way is most suitable for its own unique patterns of functioning.

This open-ended approach, together with the conscious-unconscious double bind, is also the essence of one of Erickson's approaches to resistant patients. When combined with ideomotor signaling (as will be described in a later section) to indicate when the unconscious has made a satisfactory response or answered a question, the conscious-unconscious double bind becomes a reliable way of evoking hypnotic or involuntary responses in a manner that is usually acceptable to even the most resistant, frightened, or misinformed subject. In general, all the double bind approaches are excellent means for helping the so-called resistant patient bypass or resolve the erroneous ideas and the limitations of his belief system that have been impeding hypnotic responsiveness and therapeutic change.

Erickson introduced a series of interrelated double binds in this session that were all directed toward depotentiating conscious sets by emphasizing the potency of the unconscious over consciousness. Consider the following:

But your conscious mind will keep it only with the consent of your unconscious mind.

You don't need to listen to me. Your unconscious mind can listen to me without your knowledge.

A person seeking therapy conies in and tells you one story that is believed fully at the conscious level and in nonverbal [unconscious] language can give you a story that is entirely different.

And the unconscious mind has had little opportunity to give recognition to its own ways of understanding. [Implying it would be well to give the unconscious that opportunity now.]

And your willingness to rely upon your unconscious mind to do anything that can be of interest or value to you as most important.

Now there are many different ways in which the mind can function in which the unconscious can join with the conscious. Many different ways in which the unconscious can avoid the conscious mind without the conscious mind knowing that it has just received a gift.

If the reader studies the context of these remarks, it will be found that they are usually directed toward freeing the patient's capacity for functioning on an unconscious level to explore the many response potentials that have been excluded by consciousness. Learning to experience trance and the response potentials that are available in trance is thus directly related to the patient's ability to let go of the directing and limiting functions of his usual frames of reference. Erickson demonstrates an important approach to separating conscious from unconscious processes at the end of this session. He typically distracts patients for at least two to five minutes after the formal termination of trance because, unless a patient has been trained otherwise, it usually takes that long to fully separate trance and waking states. The distraction period allows the associative connections to trance events to be broken. Being so broken, trance events tend to remain amnesic. This also helps make a recognizable demarcation between trance and wakefulness. This recognizable demarcation thus automatically ratifies the fact that the trance was "real."

We view the typical experimental approach to hypnosis where the investigator administers a standard scale of direct suggestions and then immediately questions subjects about their experience as being destructive of the unique aspects of the first stages of learning how to experience trance. Such immediate questioning blurs the still delicate distinction between trance and waking states in subjects who are just learning how to let themselves experience trance. The experimenter's immediate questions unwittingly build associative bridges between the contents of the trance and the awake state. *These associative bridges actually destroy the experience of trance as an altered state that is discontinuous from the ordinary awake state.* It is an odd but sadly true fact that consciousness usually does not recognize when it is in an altered state; people must learn to recognize the delicate and nascent experience of developing trance just as they must learn to recognize any other altered state (due to alcohol, drugs, toxemias, psychosis, etc.). It is well established that the process of observation frequently interferes with the observed process. This is particularly true for psychology in general and hypnosis in particular. Making injudicious direct observations usually interferes with the trance phenomenon being investigated.

4. The Double-Dissociation Double Bind

Erickson introduces another more complex double bind in this session to facilitate dissociation. Note the subtle interlocking of the following suggestions for dissociation that seem to cover all possibilities of response, while at the same time introducing the possibility of certain posthypnotic responses.

You can as a person awaken but you do not need to awaken as a body. (Pause)

You can awaken when your body awakes but without a recognition of your body.

In the first half of this statement awakening as a person is dissociated from awakening as a body. In the second half awakening as a person and body are dissociated from a recognition of the body. Because of this we may call this type of statement a double-dissociation double bind. So complex is the total effect of this suggestion that it is not immediately obvious just what response possibilities are being suggested. The actual response possibilities are as follows:

a. You can as a person awaken, but you do not need to awaken as a body.
b. You can as a person awaken, but you do not need to awaken as a body and recognize your body.
c. You can as a person awaken, and you can as a body awaken, but without a recognition of your body.

Hypnotic forms such as the double-dissociation double bind have an exciting potential for *exploring an individual's response abilities* as well as mediating suggestions. As with open-ended suggestions, double-dissociation double binds permit a certain amount of free choice that enables a subject's individuality to express itself in ways that are surprising even to the subject. Double-dissociation double binds tend to confuse subjects' conscious mind and thus depotentiate their habitual sets, biases, and learned limitations. Under these circumstances the field is cleared for the possibility of creative processes to express themselves in a more autonomous and unconscious manner. We know from studies in neuropsychology (Luria, 1973) that the secondary and tertiary association areas of the parieto-temporo-occipital context are capable of synthesizing and mediating the same psychological function in many different ways. Hypnotic forms such as the double-dissociation bind may enable the subject to exercise and utilize the incredible potentials of these association areas in ways that are entirely new and outside the range of the subject's previous experience. Understood in this manner, the double-dissociation double bind can be explored as a means of enhancing creativity rather than simply programming suggestions.

Other examples illustrating possibilities of the double-dissociation double bind are as follows:

You can write that material without knowing what it is then

you can go back and discover you know what it is without knowing you've done it.

Formulations such as the above for automatic writing with or without either a recognition of its meaning or that one has written it are not as arbitrary as they may seem. Studies of the secondary zones of the occipital cortex and optico-gnostic functions (Luria, 1973) illustrate that each of the above possibilities can occur naturally in the form of agnosias when there are specific organic disturbances to brain tissues. Each of these agnosias is possible only because a discrete mental mechanism for normal functioning has been disturbed when it appears. The agnosias are thus tags for identifying discrete mental mechanisms. A so-called suggestion in the form of a double-dissociation double bind may be utilizing these same natural mental mechanisms. We hypothesize that these mental mechanisms can be turned

on or off in trance even though they are usually autonomous in their functioning when a person is normally awake. From this point of view we can conceptualize "suggestion" as something more than verbal magic. Adequately formulated hypnotic forms actually may be utilizing natural processes of cortical functioning that are characteristic of the secondary and tertiary zones of cerebral organization. These processes are synthetic and integrative in their functioning and are responsible for processes of perception, experience, recognition, and knowing. Constructing hypnotic forms that can either block or facilitate these discrete mechanisms of the secondary and tertiary zones thus has the potential for vastly extending our understanding of cerebral functioning. This may be the neuropsychological basis for using hypnotic forms for altering human behavior and greatly expanding all forms of human experience.

5. A General Hypothesis About Evoking Hypnotic Phenomena

Hypnotic forms such as the double-dissociation double bind also suggest a more general hypothesis about the means by which traditional hypnotic phenomena can be evoked by dissociation, providing another hint about how new hypnotic phenomena can be developed. We may hypothesize that in general a hypnotic phenomenon takes place simply by dissociating any behavior from its usual associational context. In our previous example Erickson demonstrated how awakening as a body can be dissociated and separated from its usual associational context of awakening as a person. When he demonstrates how not recognizing one's body can be effected by dissociating the ability to see (or recognize one's body) from its usual associational context with awakening as a person, he is actually demonstrating how a negative hallucination can be evoked by a process of dissociation.

In a similar manner the traditional hypnotic phenomena of catalepsy can be evoked by dissociating the ability to move a part of the body from its usual associational context of awakening; anesthesia by dissociating the ability to feel; amnesia by dissociating the ability to remember; and so on. The classical hypnotic phenomena of age regression, automatic writing, hallucinations and time distortion can all be understood as "normal" aspects of behavior that take place in an autonomous or hypnotic manner simply by separating them from their usual associational contexts. It is now an exercise for the therapist's ingenuity to locate those associational contexts from which any of these traditional behaviors can be dissociated to evoke hypnotic phenomena in any particular patient. We can naturally expect that there will be individual differences in the strength with which these various behaviors are attached to different associational contexts in different subjects. The therapist's task is to determine which behaviors can be most easily dissociated from which contexts in which patients. Whenever a behavior is successfully dissociated from its usual context, we have evoked a hypnotic phenomenon. As the therapist develops a facility for this approach, there will be room for evoking entirely new effects that have not yet been reported in the literature. An infinite number of hypnotic phenomena can be evoked for the purposes of basic research and therapy.

6. The Reverse Set Double Bind

Erickson learned something about the reverse set double bind as a boy on the farm. He recounts the events as follows: (Erickson and Rossi. 1975).

My first well-remembered intentional use of the double bind occurred in early boyhood. One winter day with the weather below zero, my father led a calf out of the barn to the water trough. After the calf had satisfied his thirst, they turned back to the barn but at the doorway the calf stubbornly braced its feet and, despite my father's desperate pulling on the halter, he could not budge the animal. I was outside playing in the snow and, observing the impasse, began laughing heartily. My father challenged

me to pull the calf into the barn. Recognizing the situation as one of unreasoning stubborn resistance on the part of the calf, 1 decided to let the calf have full opportunity to resist since that was what it apparently wished to do. Accordingly I presented the calf with a double bind by seizing it by the tail and pulling it away from the barn while my father continued to pull it inward. The calf promptly chose to resist the weaker of the two forces and dragged me into the barn.

Psychiatric patients are often resistant and withhold vital information indefinitely. When I observe this I emphatically admonish them that they are not to reveal that information this week, in fact, 1 am insistent that they withhold it until the latter part of next week. In the intensity of their subjective desire to resist, they fail to evaluate adequately my admonition; they do not recognize it as *a double bind requiring them both to resist and to yield.* If the intensity of their subjective resistance is sufficiently great they may take advantage of the double bind to disclose the resistant material without further delay. They thereby achieve their purpose of both communication and resistance. Patients rarely recognize the double bind when used on them, but they often comment on the ease they find in communicating and handling their feelings of resistance.

The reverse set double bind permits the subject both to resist and to yield! People with problems are, in fact, usually caught between conflicting impulses. They are caught in ambivalence between resisting and yielding to various impulses and trends within themselves. An effective approach to resolving this dilemma is to allow both the resistance and the yielding to be expressed. It does not make sense from a rational point of view—but it does make sense from an emotional point of view—to free and express all the impulses that were previously locked in mutual contradiction. A clear example of Erickson's use of the reverse set to cope with contradictory, defiant, negativistic, and resistant behavior was reported as an illustration of his utilization of the subject's own behavior to initiate trance (Erickson, 1969). The first step is to carefully challenge the subject in such a way that a reverse set is established; the subject is provoked to do the exact opposite of what Erickson says. He then gradually introduces a series of suggestions the reverse of which will lead the subject to experience trance.

The writer's utterances were carefully worded to elicit either verbally or by action an emphatic contradiction from the heckler, who was told that he had to remain silent; that he could not speak again, that he did not dare to stand up; that he could not again charge fraud; that he dared not walk over to the aisle or up to the front of the auditorium; that he had to do whatever the writer demanded; that he had to sit down; that he had to return to his original seat; that he was afraid of the writer; that he dared not risk being hypnotized; that he was a noisy coward; that he was afraid to look at the volunteer subjects sitting on the platform; that he had to take a seat in the back of the auditorium; that he had to leave the auditorium; that he did not dare to come up on the platform; that he was afraid to shake hands in a friendly fashion with the writer; *that he did not dare to remain silent',* that he was afraid to walk over to one of the chairs on the platform for volunteer subjects; that he was afraid to face the audience and to smile at them; that he dared not look at or listen to the writer; that he could not sit in one of the chairs; that he would have to put his hands behind him instead of resting them on his thighs; that he dared not experience hand levitation; that he was afraid to close his eyes; that he had to remain awake; that he was afraid to go into a trance; that he had to hurry off the platform; that he could not remain and go into a trance; that he could not even develop a light trance; that he dared not go into a deep trance, etc.

The student disputed by word or action every step of the procedure with considerable ease until he was forced into silence. With his dissents then limited to action alone, and caught in his own pattern of contradiction of the writer, it became relatively easy to induce a somnabulistic trance state. He was then employed as the demonstration subject for the lecture most effectively.

The next weekend, he sought out the writer, gave an account of his extensive personal unhappiness and unpopularity and requested psychotherapy. In this he progressed with phenomenal rapidity and success.

This technique, in part or *in toto,* has been used repeatedly in various modifications, especially with defiant, resistive patients, particularly the "incorrigible" juvenile delinquent. Its significance lies in the utilization of the patient's ambivalences and the opportunity such an approach affords the patient to achieve successfully contradictory goals, with the feeling that these derived out of the unexpected but adequate use of his own behavior. This need to meet fully the demands of the patient, however manifested, ought never to be minimized.

7. The Non Sequitur Double Bind

Erickson uses non sequiturs or illogic as double binds. Non sequiturs and illogic tend to bind, immobilize or disrupt a person's conscious sets so that choice and behavior tend to be mediated on a more involuntary level. To the child who does not want to go to bed he might first employ a time bind:

Would you rather go to sleep at 8:00 or 8:15?

Of course the child chooses the lesser of the two evils and agrees to go to bed at 8:15. If there is any further difficulty, Erickson might employ an illogical but convincing double bind such as: "Do you wish to take a *bath* before going to bed, or would you rather put your pajamas on in the *bathroom!"* In such a non sequitur double bind there is a similarity in the content of the alternatives offered even though there is no logical connection. One could get vertigo trying to figure out the sense of such a proposition. Even though it is impossible to figure out, one tends to go along with it when it is expressed in a confident and convincing manner.

8. Contrasting the Therapeutic and Schizogenic Double Bind

The relation between Erickson's therapeutic use of the double bind and the studies of it by Bateson et al. (1972) in the genesis of schizophrenia offers an interesting study of similarities and *contrasts.* We may list them side by side for comparison.

	The Bateson Schizogenic Double Bind	The Erickson Theraputic Double Bind
1.	*Two or more persons:* The child "victim" is usually ensnared by mother or a combination of parents and siblings	*Two or more persons:* Usually patient and therapist are ensconced in a positive relationship.
2.	*Repeated experience* of the same double bind rather than one simple traumatic event.	*One or more forms:* of the double bind are offered until one is found that works.
3.	*A primary negative injunction:* "Do not do so-and-so or I will punish you."	*A primary positive injunction:* "I agree that you should continue doing such and such."
4.	*A secondary injunction conflicting with the first at a more abstract [meta] level, and like the first, enforced by punishments or signals that threaten survival.*	*A secondary positive suggestion at the more abstract level that facilitates a creative interaction between the primary (conscious) and metacommunication (unconscious).*
5.	*A tertiary negative injunction prohibiting the victim from escaping the field.*	*A tertiary positive understanding (rapport, transference) that binds the patient to his therapeutic task but leaves him free to leave if he chooses.*
6.	Finally, the complete set of ingredients is no longer necessary when the victim has learned to perceive his universe in double bind patterns.	*The patient leaves therapy when his behavior change frees him from transference and the evoked double binds.*

It may be noted in summary that the schizogenic double bind uses negative injunctions that are enforced at the metalevel, or abstract level, which is outside the victim's control and from which there is no escape. Watzlawick, Beavin, and Jackson (1967) have illustrated the therapeutic application of the double binds closely modeled on Bateson's formulation wherein the patient is bound to a course of behavior change with no means of escape. Such double binds are admittedly difficult to formulate, however. Erickson's double binds, by contrast, appear to be looser in their formulation on the primary message level but more complex in utilizing many

aspects of the patient's unconscious dynamics simultaneously on the metacommunicative level. Erickson's therapeutic double binds always emphasize *positive agreement on the level of metacommunication while offering possibilities that can be refused on the primary message level if they are not appropriate.* Erickson has stated, "While I put the patient into a double bind they also sense, unconsciously, that I will never, never hold them to it. They know I will yield anytime. I will then put them in another double bind in some other situation to see if they can put it to constructive use because it meets their needs more adequately." For Erickson, then, the double bind is a useful device that *offers* a patient possibilities for constructive change. If one double bind does not fit, he will try another and another until he finds one that does.

9. The Unconscious and Metacommunication

Throughout this discussion of the varieties of double bind the reader may have noted the ease with which we could use the terms "unconscious" and "metacommunication" in the same place. These terms may in fact be in the process of becoming interchangeable. This suggests we may be witnessing a fundamental change in our world view of depth psychology whereby we are developing a new and more efficient nomenclature. Philosophers have never liked the term "unconscious", it was the academic and philosophical rejection of this term that impeded the early acceptance of Freud's psychoanalysis. The use of the term "unconscious" still divides academic and experimentally oriented psychologists from clinicians as well as doctors in physical medicine from psychiatry. The term "metacommunication", however, was developed within a mathematicological framework, and as such, it fits in with the world view of the research scientist as well as the clinician. It may well be that we are on the threshold of a new Zeitgeist wherein we will revise the terms of depth psychology to make for a better fit with current conceptions in mathematics, cybernetics, and systems theory.

Exercises with Double Binds

1. Construct your own original list of a variety of double binds with a positive metacommunication to do the following:

a. structure a trance situation
b. structure each of the classical hypnotic phenomena
c. ratify trance
d. structure therapeutic alternatives for a variety of clinical problems (e.g., phobias, compulsions, depression, anxiety, habit problems).
e. structure corrective action in various emergency situations
f. structure learning, creative imagination, and problem solving g. structure relations between the conscious and unconscious
h. devise experimental situations to test which of your original double binds are most effective

2. Explore the dynamics of double binds with negative metacommunications that engender the following:

a. competitive situations
b. exploitive situations (economic, social, etc.)

3. What experimental situations can you devise to explore the relation between double binds and such sociological catastrophes as wars and depressions and such psychological problems as neurosis, psychosis, and phobias?

OPEN-ENDED SUGGESTIONS

Erickson ends the commentary to this session with an important admission. He frequently uses a buckshot approach that offers the patient many possibilities of response in an open-ended manner; thus, the patient's own unconscious can select just what experience is most appropriate at that time." How different this is from the older authoritarian approaches that belabor the patient with highly specific direct commands and suggestions! By offering suggestions in such manner, he achieves three important goals:(l) There is no possibility of a patient failing on a suggestion since all responses are defined as admissible hypnotic phenomena; (2) patients' response abilities (the "response hierarchy") are explored to provide clues as to what behaviors are available for the achievement of therapeutic goals; (3) since anything the patients do is defined as an adequate hypnotic response, they cannot resist or withdraw from the situation. Whatever they do tends to propel them further into the hypnotic situation of following suggestions.

In his 1964 paper on his technique with resistant patients, for example, Erickson manages to effect a dissociation between the conscious and unconscious while defining practically any possible response on the conscious level as a valid hypnotic phenomenon. In part it runs as follows:

"Now when you came into this room you brought into it both of your minds, that is, the front of your mind and the back of your mind." ("Conscious mind" and "unconscious mind" can be used, depending upon the educational level, and thus a second intimation is given of dissociation.) "Now, I really don't care if you listen to me with your conscious mind, because *it doesn't understand your problem* anyway or you wouldn't be here, so *I just want to talk to your unconscious mind* because it's here and close enough to hear me so you can let your conscious mind listen to the street noises or the planes overhead or the typing in the next room. Or you can think about any thoughts that come to your conscious mind, systematic thoughts, random thoughts because *all I want to do is to talk to your unconscious mind and it will listen to me* because it is within hearing distance even *if your conscious mind does get bored* (boredom leads to disinterest, distraction, even sleep)."

In these few sentences the reader can observe not only how these suggestions admit and define practically anything the conscious mind can do as a valid hypnotic response, but also Erickson's simultaneous use of truisms, dissociation, implication, double binds, and finally even an approach to depotentiating consciousness with boredom. This open-ended approach of simultaneously using many possible means of effecting trance and suggestions is highly characteristic of Erickson's style. We will study many illustrations of this open-ended approach in each of the following sessions.

Exercises with Open-Ended Suggestions

1. Begin the practice of formulating suggestions in an open-ended manner that admits and defines any possible responses as acceptable. This is particularly important in the induction of trance, where both the therapist's and patient's fears of failure are most pronounced. Formulating induction suggestions in an open-ended manner allows both parties to relax. A premium is placed on exploration and on a convergence of expectations in the patient and therapist that greatly facilitates rapport and therapeutic progress. (Sacerdote, 1972).

2. When in doubt about where a patient is in trance or what can be experienced, formulate suggestions in an open-ended manner that admits any *kind* of response as adequate.

3. When in doubt about a patient's readiness to experience a particular phenomenon, formulate open-ended suggestions that admit any degree of that response as adequate. It will be useful for the beginning hypnotherapist to know and learn to recognize all possible degrees or increments of response for all the classical hypnotic phenomena.

4. Learn to formulate therapeutic suggestions in an open-ended manner that admits no possibility of failure.

SUGGESTIONS COVERING ALL POSSIBILITIES OF A CLASS OF RESPONSES

Closely related to open-ended suggestions, but opposite in direction, are suggestions that are carefully formulated to cover all possibilities of a class of responses. While open-ended suggestions accept any response as valid, suggestions covering all possibilities of a class of responses usually restrict the patient to a narrow range of acceptable possibilities. The open-ended suggestion admits an essay of any possible response that allows the patient's originality to become manifest. Suggestions covering all possibilities of a class of responses restrict the patient to a relatively narrow range of choices within which he can respond. Erickson (1952) illustrates this approach in his hand levitation technique of induction as follows:

Shortly your right hand, or it may be your left hand, will begin to lift up, or it may press down, or it may not move at all, but we will wait to see just what happens. Maybe the thumb will be first, or you may feel something happening in your little finger, but the really important thing is not whether your hand lifts up or presses down or just remains still; rather, it is your ability to sense fully whatever feelings may develop in your hand.

While open-ended suggestions are useful in exploring a patient's response potentials, the suggestions that cover all possibilities of a class of responses are more useful when we wish to funnel a patient's responses in one definite direction. To move a subject in the direction of experiencing anesthesia, for example, one could proceed with suggestions covering all possibilities of a class of responses somewhat as follows:

Now you can notice just where that arm is feeling something and where it is not. Just where it may tingle or be numb or not feel anything at all.

When the patient indicates there are areas where the arm is numb or without sensation, the therapist can then proceed with exploratory questions that allow the anesthesia to spread to the desired area. To explore the possibility of alterations in visual perception and for positive or negative hallucinations one could proceed somewhat as follows:

And now or in a few moments when your unconscious is ready there may be a blankness or a haziness in your visual field. (Pause) And how will that haziness develop? Will there be a fog or shadows? And when will the shadows begin to arrange themselves into definite forms? (Pause) Will your eyes be open or closed? (Pause) It will be interesting to find out whether it will be hazy or foggy or blurred. Or will things be unusually bright, sharp, and clear when you open your eyes? Will there be an alteration of the color background? Will some things be unusually clear and other things not seen at all? You can wonder and wait comfortably as that develops.

This series of suggestions admits just about any possibility of a response in altered visual perception as a successful and interesting experience. It helps patient and therapist explore what response potentials for altered perception are available to the patient at this particular time and place.

Exercises in Covering All Possibilities of a Class of Responses

1. Plan how you could formulate suggestions covering all possibilities of a class of responses to funnel the patient's responsivity toward the experience of each of the classical hypnotic phenomena. (Erickson provides an unusually clear example of this with time distortion in the next chapter.)

2. It can be interesting to practice suggestions covering all possibilities of a class of responses in common everyday situations such as dining, recreation, shopping and so on. Suggestions outlining the possibilities of the *what, where* and *when* of such activities can enhance freedom of choice for your partner.

IDEOMOTOR SIGNALING

Ideomotor signaling may be the most useful hypnotic form discovered within the past half-century. Erickson (1961) has reviewed the series of discoveries that led him from the use of automatic writing to his development of hand levitation and finally ideomotor signaling during the 1920s and 1930s. Erickson (1964c) has outlined a complete introduction to ideomotor signaling for facilitating trance induction, trance deepening, and communication in trance with the following words. The italics are placed by Erickson to make clear to the reader where indirect suggestions are being made. The reader should be able to recognize where conscious-unconscious double binds are being formulated.

"Something everybody knows is that people can communicate verbally ["talk by words" if warranted by low educational or intelligence level] or by sign language. The commonest sign language, of course, is when you *nod your head yes or no.* Anybody can do that. One can signal 'come' with the forefinger, or wave 'bye-bye' with the hand. The Finger signal in a way means 'Yes, come here,' and waving the hand means really 'No, don't stay.' In other words one can use the head, the finger or the hand to mean either yes or no. We all do it. *So can you.* Sometimes when we listen to a person we may be *nodding or shaking the head not knowing it* in either agreement or disagreement. *It would be just as easy to do it with the finger or the hand.* Now I would like to ask your unconscious mind a question that can be answered with a simple yes or no. It's a question that *only your unconscious mind can answer.* Neither your conscious mind nor my conscious mind, nor, for that matter, even my unconscious mind knows the answer. *Only your unconscious mind knows* which *answer can be communicated,* and it *will have to think either a yes or a no answer. It could be by a nod or a shake of the head, a lifting of the index finger,* let us say, the right index finger for the yes answer, the left index for a no since that is usually the case for the right-handed person and vice versa for the left-handed person. *Or the right hand could lift or the left hand could lift. But only your unconscious mind knows* what the answer will be when I ask for that yes or no answer. And not even your unconscious mind will know, when the question is asked, whether *it will answer with a head movement, or a finger movement,* and *your unconscious mind will have to think through that question* and *to decide, after it has formulated its own answer, just how it will answer."* (All of this explanation is essentially a series of suggestions so worded that responsive ideomotor behavior is made contingent upon an inevitable occurrence, namely, that the subject *"will have to think"* and *"to decide"* without there being an actual request for ideomotor responses. The implication only is there, and implications are difficult to resist.)

We believe that for such ideomotor signaling to be truly autonomous and unconscious, patients should be in trance or distracted in one way or another so they will not have an opportunity to observe their own movements. Because of this Erickson frequently prefers to look for automatic head nodding or shaking where patients are least likely to observe themselves. It is surprising how often patients will nod or shake their heads to contradict their own verbal statements even without any formal instruction about ideomotor signaling. Frequently it is a *very slow and slight* but persistent head nodding or shaking that distinguishes the movements as coming from an unconscious level. These slow, abbreviated movements should be distinguished from *larger and more rapid* head movements that are more consciously used as a way of emphasizing what is being said verbally.

We prefer to utilize a patient's own natural means of ideomotor signaling whenever possible. Whatever natural and automatic movements a patient makes in ordinary conversation can be studied for their metacommunicative value. Besides the more obvious head and hand movements, eye blinking (slow or rapid), body shifting, leg movements, arm position (e.g., crossed over one another as a "defense"), lip wetting, swallowing, facial cues such as frowning and tensions around the mouth and jaw can be studied for their commentary on what is being said verbally.

Since Erickson's introduction of ideomotor signaling other investigators (Le Cron, 1954; Cheek and Le Cron, 1968) have explored its usefulness in facilitating a variety of hypnotic phenomena. A most important aspect of sound hypnotic work is to know where the subject is at all times. Many subjects are reluctant to speak in trance, and when they do so their usual patterns of waking associations and behavior may be aroused, thus tending to suppress the autonomous aspects of trance experience. Ideomotor signaling appears to be a response system that can function more autonomously than speech. As such, ideomotor signaling is a more convenient form of communicating during trance. Subjects comment that it is easier to move a finger or hand or nod a head in trance than to talk. It tends to ratify the reality of their trance as an altered state when they realize their ideomotor signals are autonomous: they are experienced as taking place spontaneously without making any conscious effort to move.

In practice there are many possible relations between awareness, volition and ideomotor signals. Initially many subjects realize they "know" or can "feel" what movement will take place before it does. Because of this they are not certain whether the ideomotor movement was truly autonomous or whether they actually helped it. With deepening experience of trance there is less awareness of the movements, and they are accepted as being more truly autonomous. With other subjects, perhaps those who are already experiencing trance without realizing it (the "common everyday trance" wherein one's attention is fixed and focused so that the surrounding reality is ignored, such as when one is absorbed in listening to an interesting speaker, watching a movie, reading a book), the ideomotor movements come autonomously entirely as a surprise. These subjects are fascinated with them and wonder what responses will be given. The ideomotor movement obviously comes before they "know" what the answer will be. Other subjects tend to experience *ideosensory* responses before the actual ideomotor movement. They will "feel" an itch, prickliness, warmth, or some other sensation in the finger before it moves.

An uncritical view of ideomotor signaling takes such movements as the "true response of the unconscious." This is particularly the case when patients say one thing verbally but contradict themselves with ideomotor signals. Although there is much clinical experience to suggest that such contradictions are important clues about conflicts that the patient may not be aware of, there is to date no controlled experimental research that confirms this view. Because of this it is better at this stage of our understanding to view ideomotor signals simply as another response system that must be studied and checked—just as any other verbal or nonverbal form of communication must be. Ideomotor signals are particularly interesting in trance work because they are a system of communication that is compatible with the autonomous aspects of trance experience.

Exercises With Ideomotor Signaling

1. Study the historical aspects of ideomotor signaling in the form of the thought reading experiments of the 19th century (Drayton, 1899), mediumistic phenomena such as table turning and the Ouiji board (Bramwell, 1921), the Chevreul pendulum (Weitzenhoffer, 1957), etc. Much of the so-called occult and psi phenomena may be understood as involuntary muscular movements and ideomotor and ideosensory responses that are unconsciously sent and received.

2. Study all varieties of apparently involuntary muscular movements as forms of ideomotor signaling in everyday life. Notice how people will unconsciously nod or shake their heads and move their lips, hands, and fingers when engaged in internal dialogue. Learn to

read faces; learn to recognize the minute facial movements that indicate changes in mood and feeling. Study body posture and movements as nonverbal forms of communication (Birdwhistell, 1952, 1971; Scheflen, 1974).

3. Plan how you can introduce ideomotor signaling as a natural form of autonomous communication during trance in ways that can fit the individuality of each patient.

4. Learn to formulate suggestions so that the patient will give ideomotor signals when an internal response (experiencing warmth, anesthesia, hallucinations, etc.) has been experienced. Ideomotor signals can be combined with the implied directive (see Chapter 5) to set up a communication system that can greatly facilitate trance training and the experience of all the classical hypnotic phenomena.

5. Plan and carry out carefully controlled clinical and experimental situations to evaluate the reliability and validity of ideomotor and ideosensory signaling.

THREE

The Handshake Induction

Erickson continues his indirect approaches in this session with the addition of his nonverbal handshake induction. A major problem in helping Dr. S learn to experience trance is to loosen the highly intellectualized and rigidly structured reality orientation she has constructed in her many years of formal education. The nonverbal techniques (Erickson, 1964a) are particularly suitable for this task since they distract and promote the confusion that Erickson now acknowledges as a basic process in his approaches to induction.

Dr. S immediately experiences catalepsy, the fogging phenomenon, restricted awareness and comfort which are among the classical indicators of trance. By the end of this session she is reviewing and possibly recovering forgotten memories; surprisingly, she is also beginning to experience a spontaneous anesthesia that was not suggested. Erickson likes to point out that it is in the spontaneous experience of such classical phenomena (along with other psycho-physiological indicators such as diminished pulse, and respiration) that can be taken as the most valid criteria for the reality of trance as an altered state.

This session brought to the fore two potent indirect approaches that were not identified earlier: conditional suggestions and compound suggestions. Erickson had been using them all along, of course, but this is the first time the Rossies have noticed them. Also noticed for the first time was his routine reliance on the ratification of trance phenomena as an indirect means of reinforcing suggestions. Erickson's use of the term "ratification" is similar but not identical to the term "reinforcement" in psychological theory. Ratification refers specifically to the patient's belief system. To ratify something means to confirm (reinforce?) that something has occurred. Specifically, in hypnotic work Erickson uses the word "ratify" with regard to hypnotic phenomenon he wants patients to experience and believe they are experiencing. To ratify the trance is to help patients realize and believe they did experience trance. To ratify the regression means that patients will later acknowledge that they did indeed experience a regression.

Confusion in the Dynamics of Trance induction

E: Now silently, mentally, count backwards from 20 to 1.

You can begin the count, now.

[Erickson shakes hands with S but lingers before releasing her hand. Gradually, and with seeming hesitation, he alternately applies and releases pressure with his fingers on different parts of her hand. S is not even sure when he finally disengages his hand. Her hand is left in a cataleptic position in midair. During this handshake Erickson looks toward her face but focuses on the wall behind her. She looks at his face and seemingly tries to capture his gaze or note whether or not he is actually looking at her. She seems a bit disconcerted by his faraway gaze.]

> E: Her disconcerted feeling is a mixture of her imperfect touch with reality. It is her intellectual awareness that something has happened and her puzzlement about what did happen. She is not really comfortable about it; she is trying to resolve it and is experiencing difficulty in resolving it. That is a sophisticated subject's reaction.
>
> R: That is an intellectually sophisticated subject's reaction to trance induction?
>
> E: Yes. That is a very common reaction.

Confusion in Trance Induction

E: Do you think you're awake? [Said without altering his faraway gaze past her.]

R: Now you ask this question that is so characteristic of you, "Do you think you are awake?" Why?

E: It means, "There is a good possibility that you are asleep and don't know it."

R: That's the implication. E: It arouses strong doubts in them, and it makes them very uncertain. If a stranger comes up to you and says, "Do you know me?" it makes you question and search through this memory and that.

R: So it puts the person in perplexity.

E: Yes, perplexity, and it emphasizes the conditional trance. It gives body to the trance.

R: I see. It begins to reinforce the trance, which her disconcerted feeling indicated was already beginning. The handshake induction wherein she is not sure when you remove your hand, then, begins a process of puzzlement about what is real and not real. The dynamics of this induction is essentially a kind *of confusion technique.*

E: Yes, it is a confusion technique. *In all my techniques, almost all, there is a confusion.* It is a confusion within them.

Unconscious Contexts as Metacommunications

S: I never really know, [laughs]

R: This immediate response reaffirms and ratifies the beginning trance.

E: When she says, "I never," she unwittingly attaches it to all other contexts with you. Only she doesn't know she is doing that. When you "don't know," you are admitting you want to know and you are willing to let the other person direct you.

R: I believe this is a very important point you are making. When she says, "I never really know" [with you], it may seem like a simple casual statement, but you believe it is an exact statement of her relation to you even though she herself does not realize the significance of her statement. Actually she is making a metacommunication; she is communicating about her communication to you. Most metacommunications are made unconsciously (Bateson, 1972).

Fogging Phenomenon

I am. I guess — I'm a little fogged up. (Pause)

E: The fogging is a dimming of reality.

Double Bind Question Implying Altered State

E: Do you really think you're awake?

E: My asking the question also implies: you're different, you are in a different state now. But she doesn't know I'm implying that.

R: The doubt you have in your voice when you ask this question turns in into a double bind: if she answers "yes" she is acknowledging only that she *thought* she was awake but must now reconsider in the light of your doubt; if she answers "no" she admits she was not awake. You are again catapulting her into trance without her knowing why. It is these *unobserved* maneuvers on your part that are so effective in inducing trance and facilitating the acceptance of suggestions. They are effective because they structure contexts (metacommunications) and initiate associations in a manner that circumvents patients' conscious sets and all their usual objections, biases, and limitations.

Structuring Self-Suggestions

S: No. [laughs] I'm really comfortable.

(Pause)

[Erickson continues to look toward her but focuses beyond.}

S: You're staring [laughs].

E: Her statement about comfort is a way of reassuring herself, you have to be altered in some way to have a reason for talking about your comfort. It also implies she is going to stay in that state and intensify it. That is what you are avoiding saying to the subject but get the subject to say themselves.

R: "I'm comfortable and I'm going to stay here and get more and more comfortable," which means going more and more into trance. It is characteristic of your approach that you structure circumstances so the patient makes the appropriate self-suggestions rather than you making a direct suggestion and risking the attendant possibility that the patient might reject it. It is much more effective if you can structure their associative processes without their awareness that you are doing it.

E: That's right. There is no need to say, "you are going in deeper and deeper."

Comfort as Characteristic of Trance

R: Now, just as catalepsy, or "stopped vision," is a characteristic of trance, would you say that comfort is a characteristic of trance?

E: Yes, because you said you're comfortable, you are going to make even the uncomfortable chair comfortable. That requires cooperative activity on your part.

R: So we can say that comfort and wanting to make yourself comfortable are characteristic of trance.

E: Yes. Since it is awfully uncomfortable to lose reality, you have to replace that reality with another.

R: That other reality is *"comfort."*

E: That is correct.

R: She also laughs at that point.

E: The laugh is a defensive reaction, and you don't have to defend yourself unless there is a threat.

R: Which is the loss of "outer" reality.

Experiencing a Limited Awareness

I feel kind of funny since my left eye muscle kind of winks closed.

E: Here she is only able to muster up enough awareness about one eye.

R: She is not cognizant of the fact that her awareness is actually limited to her left eye at this point It is from just such apparently innocuous remarks that you make important inferences about the patient's consciousness.

Structuring Expectancy to Facilitate Hypnotic Responsiveness

E: [To Dr. Rossi but without altering the faraway gaze past S.] Notice the silent waiting, the expectancy in her. So far as the patient knows you are not pressuring, you're waiting. You are letting the patient discover how she can enter the trance.

E: You can't *wait* for something without knowing it is going to happen.

R: Your waiting has the hidden implication that trance will happen. It is only an implication but it actually structures behavior without the patient being aware of it. You have structured an expectancy in her that may initiate her into a response attentativeness to any minimal changes in herself that can be the first signs of a new hypnotic experience.

Trance Indicators in Casual Behavior

[Subject plays absent-mindedly with her dress and touches the back of one hand with the other.]

You notice how occasionally she feels herself or she drags herself out of the developing trance by looking over at you?

E: She plays with her dress, but even that is not real enough now, so she goes to touching her hand.

R: This touching of herself is a stereotyped effort to reestablish the reality that is now being rapidly dissociated. Actually, it is an indication of self-absorption and a restricted awareness of anything outside herself. That, of course, is a way of defining trance experience.

Hallucination Training

Now the next thing for her to do

is actually to develop an hallucination

of, let us say, a specific landscape.

One that she has not seen previously.

But a landscape she would like.

(Pause)

Now, who knows what she would put in a landscape?

Birds, trees, bushes, rocks.

R: Why the remark about a landscape she has not seen previously?

E: I could see she was searching through her memory, but to have her make something I would like to turn her in on herself still more. By naming the specifics of birds and trees I focus her attention more closely and more narrowly. I can direct her attention without saying exactly how.

R: I've had difficulty in my beginning work with hypnosis in knowing just where the patient is. That's because I've not learned to put her in some definite place as you do. This is what you meant when you mentioned that you hold a patient firmly to her task.

Relating Conscious and Unconscious

It is very important for her to develop a specific hallucination

and to retain it

and be able to describe it.

(Pause)

E: It is very important that she do something specific here. It is important that she does something, something "specific." And for heavens sake, what is it?

R: Oh, I see, you are readying her for work now. She thinks, "I've got some important work to do. Okay, but what is it?"

E: That's right. Making her increasingly more interested in the work she will now do.

R: Is there a paradox here? In the induction the purpose was to dissociate her conscious mind so it would not interfere, yet here you are instructing it. Are you focusing the conscious on the unconscious?

E: No, the conscious mind is to give full cooperation to the unconscious. You're feeding it to the unconscious.

R: You have gathered up all her conscious awareness and are giving its energy to the unconscious?

E: Yes.

(Erickson now describes one of his current cases, where the patient's conscious mind is not yet ready to handle certain insights that are being formulated in the unconscious. The patient is producing symbolic drawings and writings that his conscious mind cannot yet understand.)

Trance Learning by Association

[Here Erickson gives a detailed 20-minute case history of a former patient who painted a landscape he saw in hypnotic trance and the relevance of this landscape for his personal dynamics. He appears to be talking to R. The subject sits quietly, apparently going deeper into trance.]

What happens in creating a hallucination related to the past?

A scene of S as a little girl

enjoying something she long ago forgot.

(Pause)

And I would like that scene to come into being,

be real.

And I want S to begin that scene,

feeling, sensing, thinking

as that situation was years ago.

And there will be no memory

of the intervening years since then.

So S can be a little girl

happily playing

something long forgotten.

And now you can regress

and enter into that.

(Pause)

[At this time S's children were actually playing outside the office in Erickson's backyard so we inside could hear their laughter and the faint hubbub of their voices].

R: You give these case histories while the patient is in a trance so they can learn by association; they learn to identify vicariously with that case history, and they tend to do similar things.

E: Yes. She had some age regression there in which she had some fantasies of her childhood and some of the wishes of her adult life and some of its realities.

Therapist's Voice in Patient's Inner Experience

In my voice you can hear

the whispering wind,

the rustle of leaves.

(Pause)

And then my voice becomes that of some neighbor,

adult friend, relative, someone known.

R: Here you merge your voice with her inner experience.

E: That's right. How do you merge your voice with a patient's inner experience? You use words that ordinary life has taught you: "the whispering wind." We have all had whispering experiences.

R: So that puts you into associative contact with something whispering and close.

E: And *close:*

E: I'm not asking her to do anything she doesn't want to. It could be a friend, relative, anyone known.

Recovering Forgotten Memories: Time Distortion

You will in due course say something

Long forgotten

now remembered.

(Pause)

A very happy memory.

And then the next year you will remember,

and the year after that,

and the year after that,

and time is passing rapidly

E: When is "in due course"?

R: It could be any time.

E: That's right.

R: You are trying to lift a specific amnesia here? You're making an effort to have her recover forgotten memories?

E: Yes.

R: With that last phrase you are adding the possibility of time distortion?

E: Yes.

Ratifying Age Regression

and you are growing

(Pause)

becoming a big girl.

E: This ratifies the regression because she can only be big now if she was little earlier.

R: Even if it was only for a fraction of a second, a mere flash of an early memory, she is now ratifying it, no matter how much or how little there was.

Focusing and Accompanying the Patient: Words with General and Specific Significance

And someday you will meet some stranger

and you will be able to tell him about it.

And when you meet that stranger,

you will tell him

about the beautiful landscape.

E: Every women has a past in which she wanted to meet a stranger.

R: You are picking up a specific motivation there.

E: But you have not defined it, you are still letting her make her own definition of it.

R: You are tapping into a very intimate channel of her mind, not just a banal or general reality. It is a general reality you know every woman has had, and yet each woman has a specific experience with a stranger. You're safe in suggesting a general category, a stranger, but it will elicit a specific memory in every woman.

E: There is a general problem for the beginning therapist here. You start patients in a train of association, but they drift along their own currents of thought and frequently leave the therapist stranded far back. Then the patient gets furious because the therapist tries to barge in—in the wrong way. He hasn't used words that allow him to accompany the patient. To do this, *we use words that have both a general and a very specific personal significance.* Every woman wants to meet a stranger in her girlhood, teenage years, her early adult life. That stranger who would eventually become someone very specific, her lover, her husband.

R: These words with both a general meaning and specific personal significance allow you to focus and accompany patients into very personal associations even though you may not know exactly what they are experiencing.

Ratifying Age Regression

And now in progression come through the years until you reach October 1972.

E: You're asking the patient to progress from time A to B and C. That ratifies that the years of A through C were real. So in a way you are ratifying the regression.

Contingent Suggestion

And when you get there when you get to the right date

(Pause)

you will arouse

with full memory.

R: When you make arousing from the trance contingent upon reaching the current date, you are again ratifying that she must have been in the past to progress to the present to wake up. In general you try to associate your suggestions with any inevitable behavior that is about to occur. One of your favorite examples is, "Don't *enter trance* (suggested behavior) until you sit all the way down in that chair" (inevitable as the patient approaches the chair). Every mother has said "Shut the door (suggested behavior) on your way out" (inevitable as Johnny approaches the door).

Dissociation Double Bind for Amnesia

You will realize

hypnosis was employed,

you will not remember going into a trance.

It isn't necessary to remember going into a trance.

(Pause)

R: This appears to be a simple dissociation double bind to facilitate an amnesia. You dissociate the memory of going into trance from its normal context of "You will realize hypnosis was employed." You then reinforce the dissociation by remarking, "It is not necessary to remember going into a trance."

Posthypnotic Suggestion for Amnesia

S: Um. [She reorients to her body by stretching a bit, touching her face, etc.]

E: Do you think you can go in a trance this morning?

S: Humm?

E: Do you think you can go into a trance this morning?

S: Uh, yeah, I guess I did. Do I think I can again?

E: Humm?

S: Yeah, I guess I could.

R: When she asks, "Do I think I can again?" it means that she realizes she was just in a trance. Therefore, your posthypnotic suggestion that she forget that hypnosis was just employed failed.

E: Except it did not really fail. — She is just "realizing" the trance. You can realize there was a yesterday but not exactly what you did yesterday.

R: Amnesia may be present for many things you did yesterday even though you realize there was a yesterday. So the general category of trance experience is recalled, but

not necessarily the specific contents. She is following your suggestion very literally when you said in the last section, that she could, *"realize* hypnosis was employed. . . you will *not remember* going into a trance." There is a subtle but very real difference between "realizing" and "remembering." You do not bother testing the amnesia at this point because she is still so close to the trance that she could build associative bridges to it and thus destroy the possibility of fulfilling your suggestion for amnesia.

E: That's right.

Questions to Locate Problems

E: What memories come to mind?

S: Being in Maine, by the ocean, looking at the starfish and things.

E: In Maine?

S: Yeah, and my uncle, a lobster fisherman, told me to get up at 5 the next morning to go out on the beach with him.

E: All right, now what has happened to you this morning?

S: I guess I went back to that scene when I was 12 years old.

E: How do you mean, you went back?

S: I guess I remembered it.

E: How tall were you?

S: five-one or five-two.

E: Why did you say your uncle?

S: Oh, he didn't talk much. I did wake up the next morning and went with him.

E: Are you awake yet?

R: Why are you asking all these specific questions here?

E: You ask specific questions in therapy when you don't know where the patient's problem is. I'm exploring I'm opening up many different aspects.

R: I see. Perhaps there was an emotional problem associated with this memory.

E: Yes. If there is a problem here, some of these questions may give her an opportunity to talk about it. But here she just treats them as straightforward questions.

Amnesia by Distraction

S: [laughs] I, I think so, yes. E: How did you go into a trance this morning? S: Well you took my hand or something. E: What's the "or something"?

S: Well, I never know what you are doing. Yes, you took my hand and looked at me.

E: Is that the best description you can give?

E: By asking her these questions I'm also facilitating amnesia.

R: How? You mean asking her how she went into trance is a distraction or an unimportant detail that is going to help her forget what actually happened in trance?

E: Yes. It's a distraction. When she is so vague as to say "or something," it indicates her memory is being contracted.

R: When she says, "I never know what you are doing," she is admitting the success of your confusion approach and the way it limits her conscious awareness.

Fogging Phenomenon

S: Yes, I think so. I'm not familiar with that. I was looking at you but got

embarrassed looking so I looked at the top of your hair. Then it started fogging up.

E: Explain that fogging.

S: Well, it kind of gets foggy. It's cloudy or foggy, not quite in focus. Like it's distant, like by the ocean it gets foggy. You can't concentrate on a point

any longer------That might have brought back that scene because that looks

like the fog of the ocean.... It was distorted for a minute. Like you could see in that glass.

[S again points out the irregularly cut glass piece on Erickson's desk which he frequently uses a fixation point for inducing hypnosis.]

Things are distorted and elongated.

E: What time is it?

S: Unfortunately, I just looked. It is 10 of 11, but it did seem longer.

R: This report of fogging was a classical sign of hypnosis in the older literature and I've recently learned that gypsies characteristically see fog or clouds in their crystal balls just before the visions. You have described it as a characteristic of the white background subjects apparently experience when they have "stopped vision" in deep trance (Erickson, 1967). What is the meaning of such fogging?

E: Fog comes in when you get away from external reality. It is a way of occluding reality. It makes you feel all alone just as you feel alone when you walk out on a foggy day.

Double Bind Question to Initiate Indirect Trance Induction

E: Do you think you're awake yet?

S: Well, I feel slightly distant but I feel basically awake I think, I don't know. Yes I am.

R: She has been awake and now you begin to cast doubt upon her awake state with this double bind question.

E: That's right.

R: The "distant" feeling she immediately describes is, of course, the first indication that another trance is beginning.

E: Going into trance is like "going away" because you are going distant from external reality.

Hand Levitation Induction:
Dissociation by Implication

E: Now direct your attention to your right hand.

(Pause)

Your right hand may have a tendency to move upward.

(Pause)

It begins to quiver and move up

toward your face.

[S's arm does begin to levitate to her face.]

(Pause)

When your hand touches your face, you can take a deep breath,

and go deeply asleep,

and be unable to lower your hand.

E: You see. she is looking *at a hand.* Where is the rest of her?

R: The implication is that she has lost the rest of her body. So this is effecting a dissociation, and a dissociation is a characteristic of trance. So as soon as this begins to take place, you've got a trance.

E: But you are not laboriously saying, "Cease to see the rest of your body."

R: Which would only arouse the typical response, "I can't". You give suggestions for dissociation by implication.

Suggestions Covering All Possibilities of a Class of Responses: Utilizing Subjective Experiences

Your arm will feel entirely comfortable,

at ease,

or it may lose all feeling,

or it may develop a wooden feeling,

a feeling of not being your arm.

I'd like to have you interested in discovering your way of handling that arm. [pause as S's hand levitates to her face.]

R: Here you give her many possible options about what her subjective experience may be as she holds her hand by her face. This allows her to utilize whatever subjective means she has to implement your suggestion. You facilitate a direct suggestion, as "be unable to lower your hand," by covering (or appearing to cover) all possibilities of subjective experience to support it. You substitute an interesting piece of self-exploration for what might otherwise be a boring or tedious task.

Catalepsy: Implication and Indirect Suggestion for Exploring Human Potentials

Of course

something has happened to your left hand,

and that will remain,

and when you awaken

you will have lost

all control of your right arm,

(Pause)

And I want you to be curious

about that dissociation of your right arm.—

the nature and character of it—

because everybody handles the situation slightly differently.

(Pause)

Your arm will remain immobile.

R: Did you notice something happening to her left hand, or was that an indirect suggestion?

E: I'm really telling her, "Let something happen to your left hand." The implication is that it will imitate the right hand. The implication is also present that she doesn't know what's happened to her left hand.

R: This indirect way of giving suggestions deepens trance.

E: It always deepens trance. S offers me the handicap of intellectual desire to keep her knowledge available for use with her own patients.

R: That's a handicap because you'd rather not have her consciousness so active. You would rather see how her individual differences are manifest in a spontaneous manner.

E: She's got to find out her differences and she can't dispute them.

R: This is fascinating! You use implication as an indirect form of suggestion to set behavior in motion that will help her explore her own individual differences in dealing with the situation. You are really not manipulating and controlling her. Rather, you are *offering* suggestions in such a way that her own unique response potentials become manifest in a manner that can be surprising and informative to both of you. Even while immobilizing her arm in what might appear to be a conventional catalepsy, you are actually leaving room for the exploration of human potentials. It is actually the subjective process by which she immobilizes her arm that will reveal whether she has a latent talent for anesthesia ("it may loose all feeling"), comfort, rigidity, ideosensory responses ("wooden feeling"), or whatever.

Posthypnotic Suggestion Contingent on Awakening

And I can count backward from 20 to 1 in any way I wish.

At the count of one you will awaken, but your arm won't.

(Pause)

20, 15, 10, 5, 4, 3, 2, 1.

R: You frequently associate awakening with a posthypnotic suggestion. This is another form of contingent suggestion in which the inevitable behavior of awakening is made contingent on the posthypnotic suggestion that "your arm won't [awaken].

Posthypnotic Analgesia from Two Mutually Reinforcing Suggestions

S: Humm. [laughs as she notices her right hand immobile by her face. She reaches up with her left hand and rubs the back of her right hand.]

E: Why did you rub it?

S: Because it feels numb.

R: It is easy to miss this "numbness" or analgesia that is unobtrusively indicated by the casual way she rubs the back of her hand. Your question about it brings the admission that it is actually numb. She is thus following a very casual suggestion for a possible analgesia you administered earlier in your "suggestions covering all possibilities of a class of responses." This posthypnotic analgesia is also a consequence of the dissociation implied in the awakening suggestions you just gave, "At the count of one you will awaken but your arm won't." This is an excellent example of how you can administer two or more mutually reinforcing suggestions to reinforce one process.

Questions for Indirect Trance Induction

E: Now what's happening to your left arm?

S: Right arm is still stiff.

E: Something is happening to your left hand.

S: [laughs as she notices her left hand getting a bit stiff and immobile.]

R: She is apparently awake at this point, but when you ask this question, is it indirectly inducing another trance?

E: Yes.

R: This seems to be an excellent way of inducing a trance in an indirect manner so that S does not even recognize a trance is being induced. You simply ask an innocent question about what's happening to her left arm. In response she cannot help but focus her attention on that arm. Your question is actually an implied suggestion that something will happen, and when something does happen (whether its a movement, an awareness of a sensation, or whatever), that something announces the beginning of a dissociation (because it appears to happen by itself without the subject's conscious volition), and dissociation, of course, is a major feature of trance experience.

E: And the subject takes credit for it. You're not telling the subject to "do this, do that." So many therapists tell their patients how to think and how to feel. That is awfully wrong.

R: It is more effective to induce the trance in a way the patient can take credit for.

Surprise to Reinforce Trance

E: It takes you by surprise?

S: It does feel a bit tingly.

E: This question is also a statement.

R: You reinforce "surprise" and by implication a state of confusion, so you—

E: reinforce the trance!

Compound Suggestion for Dissociation

E: It's going to happen, and you'll have no control over what happens.

S: I don't remember your telling me anything about it, so I don't know what's going to happen.

[Notices how left hand is getting stiffer in a midair pose]

E: [To R] You may have an idea of what's happening. [It was gradually becoming evident that her left hand was becoming immobile.]

R: This is a compound suggestion that is very typical of your style. The truism in the first part, "It's going to happen," opens a yes set that tends to facilitate acceptance of your strongly directive suggestion in the second part, "You'll have no control over what happens." The casual way you said this was so disarming that at the time I did not even recognize that you were making a strong suggestion for dissociation.

Catalepsy and Analgesia

S: Well, it feels a little strange, like my hand feels it is falling asleep or something. I'm not sure myself, but my left hand is getting a little numb too.

E: Now try to discover what is happening so you can define what is happening to that hand.

S: Well, it feels a little numb.

E: Something else is happening. S: Well, its moving a little too.

E: [To Rossi] Actually, of course, its moving around is a form of resistance at this time.

(Pause)

R: Your suggestion that she will have "no control over what happens" initiates a process of confusion and finally a catalepsy and an associated anesthesia.

E: The aside (to R) at the end is actually an indirect suggestion that something is happening.

R: I see. Your remarks to me are actually indirect suggestions to her.

Catalepsy as a Segmentation Phenomenon

You can discover what's happening to your arm through your elbow and then through your wrist.

(Pause)

You see what has happened.

First there was extreme mobility in the entire left arm,

and then less at the elbow,

and then finally growing immobility down to the wrist,

and then finally the fingers.

So your arm got fixed bit by bit.

(Pause)

Now what do you suppose is the next thing you will do?

E: Patients all have their own patterns of experiencing hypnotic phenomenon in a segmental manner. It is not important that she knows how she does it, but this sort of description allows me to stay with her. Staying with your patient is so important.

R: So this was an indirect trance induction by simply suggesting that something was happening to her left arm. What you found happening was a gradually spreading immobility (catalepsy) and numbness (anesthesia.) These responses are a highly individual matter, and much of the skill of the therapist is in discovering their spontaneous manifestation. Having established those hypnotic phenomena, you end by asking another question, "what do you suppose is the next thing you will do?" That

question sets the stage for another open-ended exploration of whatever other hypnotic phenomena she may be ready to experience.

Question Initiating Dissociation

Can you figure it out?

S: I feel a little odd at this point

E: You (R) are probably aware of what's going to happen.

(To S) Of course, you are aware that you are not fully awake.

E: If she's got to "figure it out," that affirms that something is happening.

R: She responds to your question with further dissociation indicated by the "odd" feeling.

R: These two statements catapult her into trance by fostering doubt about her mental state.

E: Yes.

Contingent Suggestion

S: Would it be all right if I put my arm down?

E: Then your eyes will shut.

(Pause)

R: This is another contingent suggestion: you associate your suggested behavior ("your eyes will shut") with an inevitable behavior that is about to occur (putting her arm down). Your suggestion rides piggyback on the patient's own motivation. You utilize her wish to do one thing to have her accept another suggestion that will maintain trance.

Trance Termination and Ratification

I want your arms to be very comfortable,

and then you can awaken comfortably,

and you can awaken only after you open your eyes.

[To R] And no matter what the trance state is, when they have had their eyes open, you have them close their eyes first and then open them to awaken. That comes from a lifetime of experience.

(S awakens and reorients to her body by stretching a bit, touching her face, patting her hair, adjusting her skirt.)

E: And how do you feel now?

S: Fine.

E: Tired?

S: No, fine.

E: Now while awake, hold your arm up in that same awkward position and see how tired it gets.

(S holds her arm up and soon acknowledges that it is getting tired.)

E: You have them close their eyes because there is a whole lifetime of experience of having their eyes closed before they awaken.

R: Again you utilize a habitual built-in mechanism for your own purpose. What experiences have you had here? Has anyone ever left your office in trance? How long have you kept people in trance?

E: People have gone out of the office and then walked back in and said, "You'd better awaken me." (Dr. Erickson now recounts a few instances where he allowed especially competent hypnotic subjects to remain in trance for as long as they required to solve a particular problem—in one case for two weeks. They would go about their normal everyday activity without anyone detecting their trance state. The purpose of the trance was to enable them to continuously work out some inner problem.)

R: You ratify the trance by having her "while awake, hold your arm up in that same awkward position and see how tired it gets." This, of course, is an instruction that contains a strong suggestion that her hand will get tired. Since the hand gets tired more rapidly when awake, that ratifies she must have been in a trance earlier.

CONFUSION IN THE DYNAMICS OF TRANCE INDUCTION

R: You said earlier that in almost all your induction techniques, confusion is something that breaks up their reality orientation. It breaks their tie to normal awakeness?

E: Yes. You know, ordinarily, what is what about yourself and the other person. When confused, you suddenly become concerned about who you are and the other person seems to be fading.

R: Confusion is an opening wedge to trance?

E: Yes. If you are uncertain about yourself, you can't be certain about anything else.

R: Actually they are getting a lot of their reality sense from you and if you throw doubt into them?

E: It spills over into their doubt about all reality. If you are uncertain about something, you tend to avoid it.

R: I see! They start withdrawing from reality if they are uncertain about it.

E: That's right! They don't know what it [reality] is.

R: If you then add to that the suggestion of a pleasant inner reality, they'd rather go to it.

E: Anything is better than that state of doubt.

R: Especially if you are up in front of an audience with everyone looking at you.

E: You want to get out of that situation, but there is no place except trance.

R: That is why hypnosis works so well in front of an audience. That is where the stage hypnotist gets a lot of his leverage.

E: Yes. He merely capitalizes on that, and he makes it deliberately unpleasant by his aggressive manner and the various tricks he employs. They will do anything to escape from that. (Erickson gives examples of how he created unpleasant situations to catapult patients into trance. Some of these are outlined in Rossi's 1973 paper, "Psychological Shocks and Creative Moments in Psychotherapy.")

R: So this confusion is the basis of many of your nonverbal pantomime techniques, would you say?

E: That's right.

R: It is the basis of staring or looking through the subject. These are all ways of disconcerting the subject, ways of making them have doubts about themselves.

E: They begin to wonder but they don't know what they are wondering about. That is very confusing!

R: Even in something as simple as eye fixation: you focus on that spot, but if you keep focusing on that spot, sooner or later your eyes are going to get tired, you are going to get blurred vision. All these things induce confusion.

E: That's right.

R: So confusion really is at the basis of all induction techniques?

E: It is the basis of all good techniques. Just as in something as simple as closing the eyes. Most workers in hypnosis do not know that as the subject closes the eyes, the subject is cutting off the visual field and is really losing something but he doesn't know what he is losing. He thinks he is just closing his eyes.

R: There are many things happening when we close our eyes, many realities we must give up.

E: In focusing on a spot you automatically cut down on peripheral vision. Then the spot gets larger as it occupies all the field of vision. You know a spot can't get larger, yet it does!

R: So that is again distorting reality and throwing them into confusion.

E: They don't know what to do. So then the therapist can tell them what to do. He lays out the ground for the subject to traverse, review, organize.

R: So can we make a summary statement that the basis of good hypnotic induction is confusion?

E: Confusion about the surrounding reality which in ordinary life is always clear. If the surrounding reality becomes unclear, they want it cleared up by being told something (e.g., I don't know where I am in this city: where am I? I don't recognize this place: what is it?).

R: That automatically tends to promote a regression, incidently. It associates them to the time when they were children and asked such questions.

E: That's right! And you are not demanding it, but you are eliciting a receptive attitude, and your most innocent question can be interpreted by them. If you know how to ask questions, you ask them in such a fashion that they will pick out the thing you want.

R: So confusion is the most basic phenomenon of induction?

E: We'll call it: The dimming of outer reality. When outer reality becomes dimmed, you get confused.

R: So we can summarize the dynamics of induction with a flow diagram:

1. Dimming of outer Reality
   ↓
2. Confusion
   ↓
3. Receptivity for Clarifying Suggestions
   ↓
4. Trance Work Proper

DYNAMICS OF THE HANDSHAKE INDUCTION

The handshake induction is one of the most fascinating and effective procedures developed by Erickson for initiating trance. It is essentially a surprise that interrupts a subject's habitual framework to initiate a momentary confusion. A receptivity for clarifying suggestions is thus initiated with an expectancy for further stimuli and direction. In a letter to Weitzenhoffer in 1961 Erickson described his approach to the handshake induction as a means of initiating catalepsy. When he released the subject's hand, it would remain fixed in a cataleptic position or would keep moving in any direction he initiated. He used this approach as a test to assess hypnotic susceptibility and as an induction procedure. The prerequisites for a successful handshake induction are a willingness on the part of the subject to be approached, an appropriate situation, and the suitability of the situation for a continuation of the experience. An edited version of his outline of the whole process and some variations is as follows.

The Handshake Induction

Initiation: When I begin by shaking hands, I do so normally. The "hypnotic touch" then begins when I let loose. The letting loose becomes transformed from a firm grip into a gentle touch by the thumb, a lingering drawing away of the little finger, a faint brushing of the subject's hand with the middle finger — just enough vague sensation to attract the attention. As the subject gives attention to the touch of your thumb, you shift to a touch with your little finger. As your subject's attention follows that, you shift to a touch with your middle finger and then again to the thumb.

This arousal of attention is merely an arousal without constituting a stimulus for a response.

The subject's withdrawal from the handshake is arrested by this attention arousal, which establishes a waiting set, an expectancy.

Then almost, but not quite simultaneously (to ensure separate neural recognition), you touch the undersurface of the hand (wrist) so gently that it barely suggests an upward push. This is followed by a similar utterly slight downward touch, and then I sever contact so gently that the subject does not know exactly when—and the subject's hand is left going neither up nor down, but cataleptic. Sometimes I give a lateral and medial touch so that the hand is even more rigidly cataleptic.

Termination: If you don't want your subjects to know what you are doing, you simply distract their attention, usually by some appropriate remark, and casually terminate. Sometimes they remark, "What did you say? I got absentminded there for a moment and wasn't paying attention to anything." This is slightly distressing to the subjects and indicative of the fact that their attention was so focused and fixated on the peculiar hand stimuli that they were momentarily entranced so they did not hear what was said.

Utilization: Any utilization leads to increasing trance depth. All utilization should proceed as a continuation or extension of the initial procedure. Much can be done nonverbally. For example, if any subjects are just looking blankly at me, I may slowly shift my gaze downward, causing them to look at their hand, which I touch as if to say, "Look at this spot." This intensifies the trance state. Then, whether the subjects are looking at you or at their hand or just staring blankly, you can use your left hand to touch their elevated right hand from above or the side—so long as you merely give the suggestion of downward movement. Occasionally a downward nudge or push is required. If a strong push or nudge is required, check for anesthesia.

There are several colleagues who won't shake hands with me, unless I reassure them first, because they developed a profound glove anaesthesia when I used this procedure on them. I shook hands with them, looked them in the eyes, slowly yet rapidly immobilized my facial expression, and then focused my eyes on a spot far behind them. I then slowly and imperceptibly removed my hand from theirs and slowly moved to one side out of their direct line of vision. I have had it described variously, but the following is one of the most graphic. "I had heard about you and I wanted to meet you and you looked so interested and you shook hands so warmly. All of a sudden my arm was gone and your face changed and got so far away. Then the left side of your head began to disappear, and I could see only the right side of your face until that slowly vanished also." At that moment the subject's eyes were fixed straight ahead, so that when I moved to the left out of his line of vision, the left side of my face "disappeared" first and then the right side also. "Your face slowly came back, you came close and smiled and said you would like to use me Saturday afternoon. Then I noticed my hand and asked you about it because I couldn't feel my whole arm. You just said to keep it that way just a little while for the experience."

You give that elevated right hand (now cataleptic in the handshake position) the suggestion of a downward movement with a light touch. At the same time, with your other hand, you give a gentle touch indicating an upward movement for the subject's left hand. Then you have his left hand lifting, right hand lowering. When right hand reaches the lap, it will stop. The upward course of the left hand may stop or it may continue. I am likely to give it another touch and direct it toward the face so that some part will touch one eye. That effects

eye closure and is very effective in inducing a deep trance without a single word having been spoken.

There are other nonverbal suggestions. For example, what if my subject makes no response to my efforts with his right hand and the situation looks hopeless? If he is not looking at my face, my slow, gentle out-of-keeping-with-the-situation movements (remember: out-of-keeping) compel him to look at my face. I freeze my expression, refocus my gaze, and by slow head movements direct his gaze to his left hand toward which my right hand is slowly, apparently purposelessly moving. As my right hand touches his left with a slight, gentle, upward movement, my left hand with very gentle firmness, just barely enough, presses down on his right hand for a moment until it moves. Thus, I confirm and reaffirm the downward movement of his right hand, a suggestion he accepts along with the tactile suggestion of left hand levitation. This upward movement is augmented by the facts that he has been breathing in time with me and that my right hand gives his left hand that upward touch at the moment when he is beginning an inspiration. This is further reinforced by whatever peripheral vision he has that notes the upward movement of my body as I inhale and as I slowly lift my body and head up and backward, when I give his left hand that upward touch."

Erickson's description of his handshake induction is a bit breathtaking to the beginner. How does one keep all of that in mind? How does one develop such a gentle touch and such skill? Above all, how does one learn to utilize whatever happens in the situation as a means of further focusing the subject's attention and inner involvement so that trance develops? Obviously a certain amount of dedication and patience are required to develop such skill. It is much more than a matter of simply shaking hands in a certain way. Shaking hands is simply a context in which Erickson makes contact with a person. He then utilizes this context to fix attention inward and so set the situation for the possible development of trance.

As he shakes hands, Erickson is himself fully focused on where the subject's attention is. Initially the subjects' attention is on a conventional social encounter. Then, with the unexpected touches as their hand is released, there is a momentary confusion and their attention is rapidly focused on his hand. At this point "resistant" subjects might rapidly withdraw their hand and end the situation. Subjects who are ready to experience trance will be curious about what is happening. Their attention is fixed and they remain open and ready for further directing stimuli. The directing touches are so gentle and unusual that subjects' cognition has no way of evaluating them; the subjects have been given a rapid series of nonverbal cues to keep their hand fixed in one position (see last paragraph of the initiation), but they are not aware of it. Their hand responds to the directing touches for immobility, but they do not know why. It is simply a case of an automatic response on a kinesthetic level that initially defies conscious analysis because the subjects have had no previous experience with it. The directing touches for movement are responded to on the same level with a similar gap in awareness and understanding.

The subjects find themselves responding in an unusual way without knowing why. Their attention is now directed inward in an intense search for an answer or for some orientation. This inner direction and search is the basic nature of "trance." Subjects may become so preoccupied in their inner search that the usual sensory-perceptual processes of our normal reality orientation are momentarily suspended. The subjects may then experience an anesthesia, a lacuna in vision or audition, a time distortion, a deja vu, a sense of disorientation or vertigo, and so on. At this moment the subjects are open for further verbal or nonverbal suggestions that can intensify the inner search (trance) in one direction or another.

Exercises in the Nonverbal Approaches

1. The keys to learning nonverbal approaches to trance induction are observation, patience, and learning one step at a time. One can begin learning the handshake induction by developing a habit of carefully observing a person's eyes and face as you are shaking hands with them in a normal way. The next stage might be to practice releasing the hand a

bit slower then usual. Then learn how to definitely hesitate in releasing the hand, carefully watching the subject's face to "read" the nonverbal responses (e.g., confusion, expectancy) to your hesitation. As your experience develops, even at this level you will begin to recognize who may be a good subject by the degree receptivity to your hesitation. The subject who "stays with you" and allows you to set the pace of the handshake is evidently more sensitive and responsive than the person who rushes off.

The next step might be only to release the hand halfway, so the subject is momentarily confused. You can then practice letting go of the rest of the hand so gently that the subject does not recognize when the release took place, the hand remaining momentarily suspended in midair. You can sometimes heighten this effect by speaking very softly so the subject's attention is further divided in trying to attend to you. The final stage is learning to add the directing touches as non-verbal stimuli for immobility (catalepsy) or movement (hand levitation). Sacerdote (1970) had described and analyzed a similar procedure for inducing catalepsy in a non-verbal manner.

2. What other non-verbal touch situations of everyday life can you learn to utilize to fix and focus attention inward to initiate trance?

COMPOUND SUGGESTIONS

I. The Paradigms of Acceptance Set, Reinforcement, or Symbolic Logic

A surprisingly simple aspect of Erickson's approach is his use of compound suggestions. The compound suggestion in its simplest form is made up of two statements connected with an "and" or a slight pause. One statement is typically an obvious truism that initiates an accepting or "yes set", the other statement is the suggestion proper. In this session, for example, when Dr. S was beginning to feel her arm getting stiff, immobile, and "tingly," Erickson reinforced the tendency toward dissociation with a compound suggestion:

E: It is going to happen

R: This is the first statement of an obvious truism since it is in fact happening as Dr. S herself demonstrates and describes.

E: and

R: The conjunctive "and" connects the two statements.

E: You'll have no control over what happens.

R: The second statement contains the suggestion proper that will reinforce her current experience of dissociation.

A much more complex compound suggestion with many implications is in the last statement Erickson makes in this session.

E: Now while awake

R: This strongly indicates that trance has terminated and reinforces her state of awakeness. Since she really knows trance has terminated, this is also a truism that opens her for what follows.

E: hold your arm in that same awkward position

R: The word "hold" implies she must make an effort, and "awkward" implies it will be difficult. This strongly sets up the likelihood that the suggestion proper, which follows, will actually happen.

E: and

R: The conjunctive "and" associates the following suggestion with the previous truisms (that she is awake and can hold her arm in that awkward position).

E: see how tired it gets.

R: The suggestion proper. Naturally she quickly acknowledges that her arm is tired, thus ratifying that the trance condition was different from the awake state. This also contains the implication that one can do different things in trance.

Other examples of compound statements are as follows.

E: Just look at one spot and I'm going to talk to you.

R: In this example the therapist has control over his own behavior ("I'm going to talk to you"), and by simply talking he can actually reinforce the suggestion, "Look at one spot."

E: There's nothing that is really important except the activity of the unconscious mind and that can be whatever your unconscious mind desires.

R: The importance of unconscious activity is suggested and then reinforced by an obvious truism of its independent activity.

E: We know the unconscious can dream and you can easily forget that dream.

R: This indirect suggestion to dream is itself a scientific truism. It is further reinforced by the truism that one can forget a dream. Merely mentioning, "You can easily forget," is also an indirect suggestion for amnesia.

E: You have altered your rate of breathing, your pulse, and your blood pressure.

Without knowing it you art demonstrating the immobility that a good hypnotic subject can show.

R: After an initial period of trance induction, when a subject is in fact very quiet, this statement about altered body functioning is a truism opening a yes or acceptance set that permits the therapist to indirectly suggest "you are ... a good hypnotic subject."

R: You can continue enjoying relaxing comfortably for a few moments and after you awaken you can relate one or two things you are willing to share, and you can let the rest remain within the unconscious where it can continue its constructive work.

R: At the end of a satisfactory hypnotherapeutic session the reward of "relaxing comfort" tends to reinforce all that happened previously while opening an acceptance set for the posthypnotic suggestion to both recall and forget. "You can let the rest remain in the unconscious" is an indirect suggestion for amnesia, permitting the unconscious to continue therapy on its own, free from the limiting and biasing influence of both the therapist's and patient's conscious sets.

It is clear from these examples that compound statements consist of two parts:

1. A truism consisting of an acceptable fact that can establish an acceptance set for the suggestion or reinforce it. If the truism has motivating properties for the patient, it is even more effective.
2. A suggestion proper that can appear before or after the truism. When the truism comes before the suggestion in a compound statement, it initiates a yes or acceptance set for the suggestion that follows. When the truism follows the suggestion in a compound statement, the truism is in a position to function as a reinforcer of the suggestion. As can be seen from the above examples, Erickson uses both forms. It will be a matter of future research to determine if both forms are equally effective. If they are, it would indicate that the commutative law (wherein the positions of the truism and suggestion may be reversed), so

common in symbolic logic, may also apply to our usage of compound statements. This would imply that these hypnotic forms follow the types of laws found in symbolic logic (Henle, 1962). If it is found that the reinforcement form (wherein the truism follows the suggestion) is more effective, then it would appear that the classical laws of learning theory are more appropriate for our understanding of compound statements in hypnosis. If it is found that the acceptance set form (wherein the truism precedes the suggestion) is more effective, then it would be evidence that positive expectancy, deemed so important by Erickson, is in fact the more significant factor in hypnotic suggestion.

COMPOUND STATEMENTS

2. The Paradigm of Shock and Creative Moments

Another provocative and interesting form of compound suggestion utilizes a model of shock and its resultant creative moment (Rossi, 1973), during which an unconscious search is initiated within the patient's associative processes. (Erickson and Rossi, 1975). A few examples are as follows.

E: Now the first step, of course, is to untangle your legs

(Pause)

and

untangle your hands.

> R: Erickson initiated hypnosis with an attractive but rigid woman with this casually offered statement that is subtly shocking because of the sexual implications of "untangle your legs." The pause allows the shock to set in and initiate a creative moment with its rapid array of indistinct, confusing, and half-formulated questions which evoke a high level of added unconscious activity searching for the "correct" implication. The second half, "untangle your hands," makes the above sex shock retroactively acceptable. The sexual allusion is now rationalized as something that was not really intended. The shock effect, however, remains in force on an unconscious level. Mentioning "untangle" a second time now shunts the high level of mental activity initiated by the sex shock into other associative networks and pathways to "untangle" and open more exploratory sets on many levels.

E: I can listen to the whispering

(Pause)

of the wind in the woods.

> R. There can be a shock reaction to the word "whispering," which, of course, has many implications on many levels (secrets, sex, etc.). The pause allows the shock and a creative moment to initiate a high level of unconscious search. The "wind in the woods" then makes the above innocuous while developing a poetic mood for allegorical work evocative of daydream, fantasy, and other trance-oriented activity.

E: Secrets, feelings, behavior, etc. you would rather not talk about (Pause)

can be examined privately and objectively in your own mind in your own trance

(Pause)

for help with the problem at hand.

> R: "Secrets" is another shock word, initiating a creative moment within the safety of trance. The pause allows the shock and inner search for highly emotional memories to

be activated. The potentially disturbing memories are then made relatively safe by now defining the situation as a "private" and "objective" evaluation. Another pause allows this safe investigation to proceed. Further positive reinforcement is then added with the final phrase assuring that this activity will "help with the problem at hand."

In these examples a pause is the critical element, allowing a creative moment to develop in response to the first shock portion of the compound statement. This first shock portion of the hypnotic suggestion is obviously most useful for initiating a high level of mental activity and search that can then be discharged into the associative networks opened by the second portion. In effect, then, this form of suggestion allows one to initiate a high level of mental activity and then focus it in a predetermined manner on a problem area.

Exercises in Compound Suggestions

1. In this section we have introduced an approach for analysing compound suggestions. It can be seen that much fundamental research needs to be done to determine whether compound statements function according to the paradigms of acceptance set, learning theory, or symbolic logic (or all three!). The researcher can explore these questions by designing and executing controlled studies to study the relative effectiveness of these paradigms. The clinically oriented reader can explore this question by constructing both types of compound suggestions for use in workshop practice to facilitate the acceptance of suggestions. It may be found that some clinicians are more effective with one form or another as a function of their personal style of verbalization, voice dynamics, and other characteristics.

2. Review tape recordings of therapy sessions to study the natural compounds in the patient's and therapist's speech. As a patient describes a personal problem, study his compounds to gain insights into the association patterns that give rise to complexes, symptoms, and so on. As the therapist talks to a patient, what patterns of ideation and behavior are being consciously or unconsciously reinforced by the natural compounds in his speech?

3. Construct hypnotic inductions designed to associate suggestions with truisms that are particularly acceptable to individual patients. Plan how the various hypnotic phenomena can also be associated with such truisms in compound statements that are easy to accept.

CONTINGENT SUGGESTIONS AND ASSOCIATIONAL NETWORKS

Another form of compound suggestion is used when Erickson arranges conditions such that a patient's normal flow of voluntary responses is made contingent on the execution of a hypnotic suggestion (the "contingent" suggestion). A hypnotic response that may be low in a patient's behavioral hierarchy is associated with a pattern of responses high on the patient's behavioral repertory and usually already in the process of taking place. Patients find that the momentum of ongoing behavior is too difficult to stop so they simply add the hypnotic suggestion as an acceptable conditional for the completion of the pattern of behavior that is already begun and pressing for completion. The contingent suggestion simply "hitchhikes" onto patients' ongoing flow of behavior. Responses that are inevitable and most likely to occur are made contingent on the execution of the hypnotic response. Erickson thus interlaces his suggestions into the patient's natural flow of responses in a way that causes hardy a ripple of demur.

The simplest form of contingent suggestion may be mother's injunction, *"Shut the door* on your way out!" as Johnny is running out the door. The already occurring flow of behavior, "on your way out" is made contingent upon "shut the door," since the mother is actually

implying, "You can't go out *unless* you shut the door." Other examples used to systematically deepen trance are as follows:

Your eyes will get tired and close all by themselves as you continue looking at that spot.

You will find yourself becoming more relaxed and comfortable as you continue sitting there with your eyes closed.

As you feel that deepening comfort you recognize you don't have to move, talk, or let anything bother you.

As the rest of your body maintains that immobility so characteristic of a good hypnotic subject, your right hand will move the pencil across the page, writing automatically something you would like to experience in trance.

Associating suggestions in such interlocking chains creates a network of mutually reinforcing directives that gradually form a new self-consistent inner reality called "trance." It is the construction of such interlocking networks of associations that gives "body" or substance to trance as an altered state of consciousness with its own guideposts, rules, and "reality."

A more complex form of contingent suggestion is in the example Erickson has used on numerous occasions in front of large groups with a subject he was inducing trance in for the first time as well as in private practice with patients who were well trained in trance. As the person approached his chair Erickson would say: "Don't enter trance until you sit all the way down in that chair, there."

Don't enter trance

E: Use of the negative "Don't" to disarm possible resistance against the suggestion to "enter trance."

until

E: A form of the contingent that now reintroduces the possibility of trance in what may be a form acceptable to the patient.

you sit all the way down

R: As part of the ongoing flow of inevitable behavior, this establishes a "yes" or accepting set for the preceding.

in that chair.

R: An acceptable directive that puts another immediate positive valence on all the preceding.

there.

E: "There" implies that if they do sit in that chair, they are accepting the choice of going into trance. It is understood that there are other chairs they can sit in and not go into trance.

This complex contingent suggestion thus follows this general paradigm: A negative -> a suggestion -> a contingent -> ongoing flow of behavior.

A classical example of an associational network built up of interlocking chains of contingent suggestions that led to a dramatic experience of visual hallucinations, amnesia, and posthypnotic suggestion was Erickson's approach to inducing trance in a "resistant" member of an audience. On one occasion, for example, a dentist urged his wife to volunteer as a demonstration subject so she could learn to experience trance. She adamantly refused

and even tried to hide in her seat behind a pillar in the auditorium. Erickson spied her and proceeded as follows:

E: I like volunteers and I also like to pick my volunteers.

R: This compound statement introduces the agreeable word "volunteer" and makes everyone a potential volunteer.

The one I'd like to pick is the pretty girl wearing the white hat who keeps hiding behind the pillar.

S: All the way from Colorado Springs my husband urged me to act as a subject. I told him I didn't want to.

E: Now, notice that you thought you didn't want to.

E: The implication of this remark is to place her not wanting to volunteer into the past with "thought you didn't want to." This phrase is also a double bind because it contains another implication: "thought you don't want to" on a conscious level can imply that you really wanted to on an unconscious level.

And now that you've come out entirely from behind that pillar, you might as well come all the way to the platform.

R: This is a contingent suggestion where "come all the way up" is hitchhiked onto her ongoing behavior of coming out from behind the pillar.

S: [As she steps forward] But I don't want to.

E: While you continue to come forward please, don't go into a trance until you sit all the way down in this chair.

E: Another contingent suggestion utilizing the negative "don't" to permit a recognition and expression of her negative attitude while yet defusing it.

As you are on the platform, you know you are not in a deep trance,

E: A truism and a reassurance that she is not in *deep* trance. This implies she may be in light or moderate trance.

but you are getting closer to that chair

E: In conjunction with the previous sentence this implies she is going into trance the closer she gets to the chair.

and you are beginning to recognize you don't care

R: "Beginning" initiates a process of inner search that now utilizes her negative "don't care" attitude . . .

whether or not you are going into trance.

R: . . .to shift her into the possibility of "you are going into trance."

The closer you get, the more you can recognize the comfort of going into a trance.

R: Another contingent suggestion to which is added the positive motivation of "comfort."

But don't go all the way in until you sit all the way down in the chair.

R: The classic contingent suggestion described earlier.

All the way down, [said as she is in the process of sitting down]

R: This is a two-level communication; it is a statement with double meaning:(l) Sit "all the way down" and (2) Go "all the way down" into trance. Her behavior of sitting down

means she is accepting the statement on level 1, but as she sits she is also without realizing it accepting the suggestion to go into trance on level 2.

E: I associated every one of her forward movements with the development of another fraction of trance by interlocking every piece of ongoing behavior with another easily acceptable suggestion.

You are all the way down in the chair all the way from Colorado Springs.

R: In a curious way this implies that every movement from Colorado Springs was an inexorable movement toward her current trance experience. This deepens the significance of her trance by giving it a long history.

You knew you did not want to go into a trance. You knew you would prefer something else. As you think it over

R: A series of three truisms leading up to the following suggestion.

there is something else.

R: A suggestion proper that again puts her on an inner search.

So why don't you look at it?

R: An open-ended question focusing her attention. This is also an indirect suggestion ("Look at") for the possible experience of a visual hallucination.

(Pause)

S: [Looking at a blank wall] I get so much pleasure watching those skiers through my kitchen window.

R: She responds literally to the above and "watches those skiers" with the "pleasure" Erickson has suggested a while back.

E: What else enhances it?

R: Another open-ended question that allows her to bring in more personally enhancing associations.

S: I always keep the hi-fi on while I watch the skiers. That is the easiest way to wash the dishes.

R: She adds the music that also belongs to her experience. The easiest way to enable hallucinatory behavior is to evoke the patient's own associations rather than an arbitrary item.

H: [At this point the husband stands up in the audience and says the following.]

Yes, she washes the dishes while watching the skiers come down the mountainside by our kitchen window.

[The husband then sends a message up to Erickson expressing the wish that he would initiate her into hypnotic training for childbirth.]

E: I think you might like to include hypnosis in your future.

R: This is an open-ended suggestion that gives her new options for future behavior.

Suppose you ask me about it after you are awake.

R: This is a posthypnotic suggestion that allows her the possibility of bringing up her own wishes and needs regarding future hypnotic work. It would be both unethical and highly destructive of the possibility of future trance work to introduce specific suggestions about hypnotic training for childbirth without first getting her request for it when she is awake.

S: [She awakens and looks around the platform.] I told my husband I would not volunteer as a hypnotic subject!

I was hiding behind that pillar and now I'm here?! I must have been in a trance.

E: Isn't it remarkable how comfortable you feel?

R: A question that is a truism (comfort is characteristic of trance) evokes positive feelings to depotentiate her reactive anger.

S: What did I do in trance?

R: Implying an amnesia.

E: You would really like to know, wouldn't you?

R: This marshals the memory-traces of her trance experience so they are ready to enter consciousness.

S: I certainly would!

E: Just look there! [As Erickson looks and points meaningfully at the blank wall she was looking at when she first hallucinated.]

S: Oh, they are skiing! [She continues actively hallucinating the skiers, describing their movements.]

R: Her strong motivation is here utilized by providing a channel for experiencing those memory traces consciously in the form of a visual hallucination with her eyes open, staring at that same wall. Trance was reinduced by a surprise approach that allowed the memory traces to discharge in hallucinatory form.

[S is then reawakened with an amnesia for this second trance.]

E: What do you suppose, when you first came up to the platform, you did in that trance?

S: (S mentions that she probably saw skiers and again repeated all the details about the skiers as if she had not discussed them before. She then goes on to wonder aloud if she might not have a use for hypnosis in the future.)

R: She is now following the posthypnotic suggestion about the possibility of including hypnosis in her future.

E: Well, you are married.

S: Well, I intend to have children. [S then discusses the possibility of utilizing hypnosis in childbirth. Years later she very successfully did so.]

R: The association about marriage naturally evokes a connection between marriage—childbirth—hypnosis.

Exercises with Contingent Suggestions

1. The value of observing regularities in patients' behavior which was emphasized in chapter 1, will now be apparent. The effectiveness of contingent suggestions depends in great part on their being appropriately timed and associated with regular patterns of ongoing behavior. The more a patient is "locked into" a certain pattern of behavior, the more powerful a vehicle will it be for the appropriately hitchhiked suggestion.

Formulate both simple and complex contingent suggestions that you could associate with any fairly automatic ongoing patterns of everyday behavior you've observed in individual patients. This can be as simple as encouraging a patient to continue any ongoing pattern of

associations or behavior. Gradually learn how to add modifying suggestions and finally suggestions to structure further therapeutic responses.

2. Plan how you could utilize simple and complex contingent suggestions for facilitating psychotherapeutic responses.

3. Construct associational networks that will facilitate hypnotic induction as well as any particular hypnotic phenomenon. Erickson's work on the construction of artificial complexes and experimental neurosis (Erickson, 1944) is of particular value for studying his method of formulating associational networks. The formulation of such associational networks may be the clearest illustration of the construction of hypnotic realities.

MULTIPLE TASKS AND SERIAL SUGGESTIONS

As we have seen, it is frequently more effective to offer two or more hypnotic suggestions rather than one. Often the momentum of doing one easy task will help a more difficult one along—as is the case with contingent suggestions.

A series or chain of interlocking suggestions is another effective method for structuring a pattern of behavior. The performance of one item serves as a cue and stimulus for the next. Erickson frequently used such series during the early years of his learning and experimentation with hypnotic realities. He would have experimental subjects in a laboratory imagine and "mentally go through the process step by step and in correct order" of reaching for an imaginary piece of fruit on an imaginary table (Erickson, 1964). If one were actually to reach out and pick up a piece of real fruit, a series of stimulus-response interactions with the real objects outside of one's skin would be required. If one performs this task mentally, however, one is interacting entirely within one's own mind with memories of sensory stimuli, perceptual patterns, kinesthetic cues, etc. This inner focus and utilization of one's own mental programs is the essence of trance experience. To put subjects on any sort of mental task requiring a series of steps utilizing their own internal programs, therefore, is another valuable hypnotic form.

Because of this Erickson frequently gives serial, multiple, or compound tasks just as he makes compound statements. His favorite word appears to be "and." "And" allows him to connect suggestions into series so that they mutually reinforce each other, while at the same time maintaining the subject within a concentrated inner focus.

The fixing and focusing of attention inward on an imaginary task is thus an indirect means of inducing trance. This inner trance-inducing focus is easily accomplished by having subjects review a series of early memories, visualizing a series of scenes or a movie (for visual types), listening to inner music (especially for those with music training), and so on. This is the basis for the fantasy and visualization approaches to inducing trance (the "house-tree-person" or "blackboard" visualizations, etc.)

A chain of casual, naturalistic suggestions forming an associational network is particularly effective for facilitating posthypnotic behavior. The following example from one of Erickson's early seminars (Erickson, 1939) is particularly effective because this series of suggestions about cigarettes is a naturalistic one in the sense that it utilizes typical patterns of behavior and motivation common to all cigarette smokers. The subject simply floats along on a natural chain of behavioral events that are already more or less built in.

After awakening the subject would (1) notice Dr. D searching vainly through his pockets for a package of cigarettes, and (2) the subject would then proffer his own pack, and (3) Dr. D absentmindedly would forget to return the cigarettes, whereupon the subject would feel very eager to recover them because he had no others.

The naturalistic or "built-in" aspect of this series of suggestions capitalizes on the automatic and partially unconscious manner with which habitual behavioral patterns are carried out. The early stages of trance training are greatly facilitated by utilizing behavioral patterns that the subject is very familiar with. These require little or no conscious effort and thus are not likely to interfere with the still fragile nature of early trance experience.

Exercises with Multiple Tasks and Serial Suggestions

1. Formulate hypnotic inductions wherein the subject is kept busy with two or more tasks. While (1) looking at that spot the subject is enjoined to (2) notice whatever sensations develop in the eyelids. While (1) watching the hand levitating (2) the unconscious can marshal all the associations and memories needed to solve a problem.

2. Formulate multiple tasks that are to be carried out on two levels, the conscious and unconscious, so that double binds become operative.

3. Formulate serial suggestions that lead step by step to the experience of dissociation and each of the classical hypnotic phenomena.

4. Formulate serial suggestions and associational networks that can facilitate posthypnotic behavior by utilizing the subject's own natural behavioral patterns.

FOUR

Mutual Trance Induction

One of Erickson's favorite methods of training a hypnotic subject is to give the novice an opportunity to observe a more experienced subject in trance. But on this occasion Erickson does something more: he orchestrates a mutual trance induction where two subjects interact in such a way that they facilitate each others' experience of trance.

In this session Erickson begins by pointing out many of the psycho-physiological indications of beginning trance. He then has an opportunity to discuss a number of other outstanding characteristics of trance: patient's subjective feelings of distance; patient's inner reality and rapport, patient's change in voice quality and learning to speak in trance. The need for careful and continual observation of the patient is further emphasized when Erickson outlines the significance of pulsations that can be observed in different parts of the patient's body. He is particularly careful to note indications of distress in the patient's behavior. There are various subtle approaches to making inquiries about this distress that will safeguard the integrity of the patient's inner balance between conscious and unconscious knowing.

Of particular significance in this session is the clarification of Erickson's view of trance as an active state of unconscious learning. He points out that it took one of his subjects (a hospitalized mental patient) 200 hours to get to the point that he was able to do something more than just sit there. Yet the patient is not expected to direct himself consciously, as is usually the case when one is awake. The learning is not of the intellectual sort that is practiced in school. The momentum for this mental activity is to come from the unconscious. It proceeds autonomously and is experiential rather than intellectual learning. Erickson points out that most of Dr. S's learning has been of the intellectual sort, but in hypnotic work she can learn best by letting go and experiencing. Learning spontaneously through one's own inner experience is then described as another way of deepening trance.

Surprise to Loosen Mental Sets

[As a surprise, Dr. H, a highly experienced hypnotic subject currently in therapy with Dr. Erickson, was invited to join R and S for this session.]

R: What is the function of surprise in your work?

E: The function of surprise is this. The patient comes to you with a certain mental set, and they expect you to get into that set. If you surprise them, they let loose of their mental set and you can frame another mental set for them.

R: You're dislodging the erroneous conscious sets that are giving them problems.

E: Yes. That's also what you do with confusion technique.

Indirect Suggestion

E: Now I'm just going to look at her. I want both of you [R and H] to observe her blink reflex.

[Pause of 30 sec. as all three watch S.]

E: In talking about S here I am actually giving her indirect suggestions. I here note many of the criteria of beginning trance as soon as she manifests them in a seemingly spontaneous manner.

R: This is one of your favorite approaches to indirect suggestion: you say things to an audience or talk about another person's experience as a way of initiating trains of associations in the patient that may eventually culminate in hypnotic responsiveness. It is an indirect form of ideomotor or ideosensory suggestion.

Ideomotor Activity in Indirect Induction: Beginning Trance Criteria

There was a slight quiver of her eyelids.

Along with that quiver is an ironing out of facial muscles.

There's an alteration in the breathing.

There's also a lowering of blood pressure.

Also a slowing of the heart rate.

There's a loss of reflexes.

She's aware that I am speaking about her to you.

Now there is a slight change in rhythm.

And she's beginning to drift

right into a deep trance state.

E: Everything I say about S is also a suggestion to H, but he did not know it. Every suggestion I made to S elicits some understanding in H, and that understanding requires that he act it out for himself to some degree.

R: That is the basic principle of ideomotor activity in hypnosis. You utilize it here to initiate an hypnotic induction in H without his being aware of it.

(Erickson here describes his typical procedure of demonstrating hypnosis with several naive subjects in front of an audience. He would surround a resistant subject with cooperative subjects, demonstrating the various phenomenon until the resistant subject was influenced by the hypnotic "atmosphere" all around him. The resistant subject would soon exhibit a "look of surprise" as he began to feel influenced and Erickson would reinforce this by remarking how "interesting" and "charming" the feelings were. Very often those who were initially afraid would go all the more deeply into trance once they got around their fear with this approach.)

Patient's Reality and Rapport

And she's removing herself from this reality

to go into a different reality

where R's reality and H's reality is changed

and mine is becoming less and less important.

And my voice?

I don't know exactly how

she hears it.

Maybe as a distant sound

which she does not feel a need to hear.

I am close enough to her

for her to hear me.

From that loss or change in body motility,

you can follow it,

it can tell you something about the character and ideation that's going through her mind.

[Mrs. Erickson was called. She comes in and is told to try to hush up S's children, who are playing loudly outside the office.]

E: To separate her from our reality (the tripart reality shared by E, R, and H) helps deepen the trance by focusing her in on her own reality.

R: I see! If the hypnotherapist is interrupted in the middle of a session and has to speak to a mailman or plumber who knocked on the door, it can deepen the patient's trance reality because they are excluded and left alone with their own internal reality.

E: I discovered the hard way. Part of my early experience was in subjects always awakening, and I had a lot of difficulty. I'd have one subject in one room and another in another room, and they would awaken when I left the room. I discovered I had to leave them in a certain way, so they would maintain their trance state. I had to assure them they were not being deserted. They could rely upon me to return to them; I was only temporarily absent. At first I told them that verbally, and later I learned how to use nonverbal cues.

R: Like what?

E: "I'm here, you are here" (Erickson demonstrates how by repeating this formula in different positions throughout the room the subject would get the idea that he was always in rapport with them, no matter where he was actually located.) When I moved away I'd say, "No matter where I am I will always be here." People don't know how much they know about the locus of a voice (Erickson, 1973).

R: It's all unconscious learning.

E: Yes. (Erickson here refers to a manuscript he was writing [Erickson, 1973] about how he actually produced seasickness in hypnotic subjects simply by changing the locus of his voice by bobbing and weaving up and down and back and forth, mimicking the changing locus a voice would have on a ship in rough waters.)

Learning to Speak in Trance

R: How are you feeling right now, S?

S: Hummm [very softly as if very far away] fine.

R: Can you describe anything of your state of awareness to us?

E: People have a lifetime of learning that talking in your sleep is socially unacceptable. It's surprising how many people fear they will betray themselves by speaking in their sleep or trance.

R: So you have to give patients special instruction and reassurance about their ability to speak in trance. And you do that simply by asking how they are feeling.

E: I've already used words like "comfort" and "fine," so when she uses the word "fine," I also know she is following my suggestions to feel comfort.

Voice Quality in Hypnosis

S: I can hear you. (Remote automaton like voice.) (pause)

R: To what do you attribute the automaton like or faraway quality of her voice?

E: It's due to a different muscle tone. Her face is ironed out, there is greater plasticity and relaxation of all the muscles, including those controlling voice.

Extraneous Stimuli in Trance

[laughs]You're tickling me. [Personal voice as if she is nearly awake.]

[Actually the microphone cord inadvertently was bobbing against her knee as R was adjusting it.]

R: That was quite by accident, it was the microphone cord. How did you experience that tickling?

S: I thought maybe you were doing it to see if I would get out of this state. [Much laughter.] I know Mrs. Erickson came in and she stepped on my toe, but it did not hurt. [Even more laughter all around.]

R: What's your state of awareness right now?

S: Oh, I'm coming awake.

R: Fully awake?

E: She has this awakening reaction because I had not given her any specific instructions to disregard all extraneous stimuli while in trance. You need to know that any alien stimulus can enter into the trance situation, and you need to learn to deal with it. Mrs. Erickson may be in a deep trance when the phone rings, and she may answer it while remaining in trance. If it's an unfamiliar voice on the phone, she will wake right up, but if she knows who it is, she may remain in trance altering her voice so the person will not notice she is in trance. But if the other person is one of my hypnotic subjects, they will recognize the trance.

Feeling of Distance in Trance

S: Oh, I'm back but slightly distant. (Pause)

E: That feeling of "distance" is a sign of trance. Nobody has really explained that sense of being distant.

R: How would you explain it?

R: Every speaker in front of an audience has a sense that the audience is with me or not with me; they are distant from me.

R: The feeling of distance then is due to feeling the lack of a shared-world-in-common (Rossi, 1972a).

E: Yes.

Depotentiating Conscious Understanding

E: S has had the opportunity of discovering she can do that work. Now I have the right to be as stupid as possible.

It isn't requisite for me

to understand all.

There can be progressive understanding on your part,

on H's part,

on the others' part.

(Pause)

And H need not be frightened

about hate

or frightened of the word: love.

You're terrified of new understandings of those words.

(Pause)

R: By saying that you "have the right to be as stupid as possible" you are making an exaggerated and humorous suggestion about how little you need to understand consciously. This implies that S and H need not use consciousness at this point either. Later they can develop their conscious understanding, but for now let the unconscious handle things. You then address a few therapeutically relevant words to H about being "frightened" and so on.

Voice Tone as a Cue

And R and S have come to join us this time.

They called to find out if they could come,

and I knew it would be to their advantage and to your advantage (H) to have them here.

R: You apparently felt from nonverbal clues that H needed some reassurance at this point so you simply talk about the pragmatic aspect of this joint session. You then emphasize that it would be to everyone's mutual advantage to be together.

E: Yes. Notice I use a different tone of voice for "your" when referring to H and a different direction of voice.

R: These voice cues are automatically and correctly interpreted by S and H, so they always know when you are referring to each even though you use the impersonal pronoun.

Other Names in Trance

Because

I could effect an interplay

that would be extremely valuable for you, for Herbie [the name previously assigned to H's personality while in hypnosis], for R, for S.

R: When you do extensive work with some patients, as you have with H, you sometimes give them another name in trance. Why?

(Erickson gives many examples from everyday life where one person—lover, mate, parent, or child—may give another person a pet name to evoke a particular mood or aspect of their relationship. A child will say "Father" or "Dad" or "Daddy" on different occasions to constellate different aspects of the relationship with father. In trance the patient may experience a particular ego state that the therapist wants to label with a special name so he can help the patient return to it later.)

Rapport in Mutual Hypnosis

[H had been watching S very carefully, presumably to study her state of awareness. At the moment Herbie is mentioned, however, his watching becomes more of a fixed stare. S seems to notice this, and they silently and deeply look into each other's eyes in a fixed, unblinking manner.]

R can watch S and you (H) can discover certain things. (Pause)

[S and H alternately blink. S's eyelids finally flutter and close, and then H's eyes close also.]

And S has made a new discovery,

but then you [H] too have made a new discovery.

(Pause)

R: You arrange a hypnotic atmosphere where both are sitting quietly in rapt attention and thus gradually developing a light trance. Now as they look at each other they automatically mimic each other's hypnotic behavior (e.g., the staring and eye blinking) and thereby go deeper into trance.

E: Yes. At this point H's distance was much greater than S's. R: You mean he was further into trance?

E: He was further away. H tended to go into a reality that included himself and me but excluding S and you.

R: So here you were trying to bring S and me into his inner reality more. But how could you tell he was tending to exclude S and me? Was he turning away from us and orienting bodily toward you?

E: A person could be looking right at you, yet you know they are not paying attention to you without their even knowing they are not paying attention.

R: Yes, they will have that faraway look in their eyes.

E: But can you define that "faraway look" in precise terms?

R: That would be difficult. Then you are saying that this comes with experience. By now it is almost an unconscious intuitive knowledge on your part.

E: Yes.

The Personal Meaning of Trance and Words

Now both of you want

profound trances

with hallucinations of the real

and of the unreal

and the organization of amorphous things.

Amorphous things, amorphous emotions, relationships,

and identities.

(Pause)

E: By saying *"both* of you want profound trances," I'm here beginning to effect a separation between them.

R: You're saying that to each of them as separate people?

E: Yes. *Each of them can have their own trance with its own individual meaning for each.* For H as a patient it is important to experience his diffuse emotions as part of his therapy. For S as a therapist in training it is important to learn to recognize amorphous emotions and relationships she will later be called upon to cope with professionally.

R: The same words will have different meanings for different people. This corresponds to your frequent use of certain words that will have different meanings at different levels within the same personality.

Time Distortion: Suggesting All Possible Responses

And when you spend time,

time can be of varying intensity.

It can be condensed,

it can be expanded,

so you can review a lifetime history in a few seconds time.

(Pause)

Those few seconds can be expanded

into

years.

Also a few days can be condensed

into a moment.

For both of you

it's a matter of your education

(Pause)

in dealing with patients

that you can take a patient's pain

and teach a patient to experience all of the pain

as a momentary passing twinge.

It can be very sharp only momentarily

even though it lasts all day.

Both of you want to learn how to expand time,

expand awareness,

and both of you need to know

that there is such a thing as

a contraction of time, feeling, pain, emotion.

A pleasing lecture of an hour's duration may seem like

it has barely begun when the hour is over.

Or in a boring lecture the chair begins to hurt,

and you get tired, and you wonder

when the hour will be up.

Both of you have had that experience in the past.

You know when you've had those experiences.

Now you're going to apply them to yourselves

in a way that helps your understanding of yourself

and your understanding of others.

(Pause)

E: Time distortion will be useful to both of them here in their different contexts.

R: You suggest all possible types of time distortion (condensation and expansion) that may operate to whatever degree the patient finds himself using. You are thus following your *basic technique of suggesting all possible responses,* so that it is almost impossible for the suggestion to fail. Whatever the patient experiences has been covered by your inclusive suggestion and can thus be counted as a success.

E: Again here the matter of education will be taken in a different way by each of them. And so on for much of this material.

R: You use common everyday truisms (that both of these well-educated subjects are certain to have experienced) to induce a "yes set" to enhance the plausibility and acceptability of your suggestions.

Trance as a State of Active Unconscious Learning

And you both realize

thoroughly

that the hypnotic state

is not really induced by me

but by yourselves.

(Pause)

And H saw S do something with her eyelids,

and then he repeated it.

And S, in watching H,

in turn repeated what H did,

and she went into a trance.

Then H went into a trance also.

As far as R is concerned

he has learned that

the proximity of one hypnotic subject to another

does the same thing as is expressed

in folk language:

Monkey see, monkey do

which is a way of understanding

children;

they see, they do.

(Pause)

There is no importance in my talking to you;

time will just pass

and I can do as I wish.

(Pause)

R: Here you are putting the responsibility for trance learning on the subjects so they will not be passively dependent on the hypnotherapist.

E: Yes. When they know they are doing it, they know they can alter their own behavior.

R: So that's an important way of reducing the magic and motivating them further in the direction of therapeutic self change. The therapist provides the patient with a setting and opportunity to do creative work. *Trance is actually an active process wherein the unconscious is active but not directed by the conscious mind.* Is that right?

E: That's right.

R: This is one of your important contributions to modern hypnosis: getting away from the automaton concept of the hypnotic state to conceptualize *hypnosis as a state of very active inner learning that takes place autonomously.* Is that right?

E: Yes.

R: In a trance state you have released the unconscious to do its own work without interference from consciousness.

E: And to do it in accord with the experimental learning of the subject.

R: Previously hypnosis was thought of as a state where the subject passively received therapeutic suggestions.

E: By being told what to do and when to do it.

R: But your approach is frequently the opposite of that. You just let the subject get into a trance state where he can do his own inner work.

Active Learning in Trance

Now each of you is learning something

pertaining to yourselves.

You are developing your own psychological techniques of psychotherapy

without knowing that you are developing them.

H now realizes

his tremendous response to the visual stimuli S gave him.

And S realizes that also.

(Pause)

R: Here, for example, you are instructing them to do their own inner learning, their own inner work for themselves. They are not just to sit there passively. Could this be some of the difficulty S is experiencing? She doesn't have the idea yet of doing her own inner work, she is being too passive.

E: She tells us she's been skipping around, just looking.

R: That's characteristic of many subjects I'm learning to work with. They are just hopping around. But that is not the state you are looking for.

E: It took one of my subjects 200 hours to learn. He would just sit there. S has been a student, a scholar. She learns intellectually, but she doesn't know how to learn something experientially. I've got to explain to her that she is to learn by experience.

Observing Pulsations

E: [to R] Notice that pulsation [in S's face].

Now I'm going to talk to R so you need not pay any attention.

R: Do you want to comment on the pulsations?

E: In watching the face in the trance state there are various places you can note the pulsation. It isn't necessary for you to use your fingers on the wrist. Use your eyes on the patient's ankle, neck, temple. Watch the changing pulsations. Often fluctuations can tell you things. You learn to correlate pulsations with muscle tonus. You can suddenly realize that increased pulsations means there exists a greater tonicity in muscles. You can't really see the muscle tonicity develop until it develops to a certain degree but from more rapid pulses you know the muscle is tighter. Now a slower pulse brings about a lessening of tonicity. Body behavior in all parts of the body should be under your observation.

Trance Distress: Indirect Questioning

E: You also look for signs of perspiration, pallor, changes in facial expression, any signs of distress. You're careful at such times.

R: When you note those distress signals you become very careful about what you are saying. It could be traumatic.

E: That's right.

R: So even while a person is in trance you are careful about what might filter into their conscious mind.

E: You don't push at such times.

R: How about when trance has terminated? Do you question them about their trance distress then?

E: Only in the most general terms. (Erickson now gives a demonstration of how he will gently imitate the head movements a patient made in trance while saying, "How about here, there, up, down, from this to that," etc.)

R: If it's safe for the conscious mind to deal with the material, consciousness will pick up your most general hints. If it is not safe, it will not understand what you're getting at.

Deepening Trance Through Spontaneous Learning

[E completely ignores H and S for about 10 minutes. He talks to R about certain manuscripts on his desk which they are working on together.]

I think I will let H awaken first.

Now H, take your time,

count backwards from 20 to 1,

awakening l/20th at each count.

Begin to count now.

(Pause)

[H awakens and reorients his body.]

Now S, I want you to begin counting silently,

mentally from 20 to 1 and begin to count now.

(Pause)

[She awakens and reorients her body.]

R: It's rather remarkable they both took the same amount of time to awaken.

E: You see, when you're working with subjects, you let them have an opportunity to experience their trance state without necessarily giving them anything to do. You leave them to their own devices. It deepens the trance. They become more aware of what they can do. They become more facile in their capacities.

R: It becomes a period of free learning for the subjects when you leave them to their own devices.

E: Yes.

R: But S has been getting irritated with you because she may not know how to deepen the trance by herself.

E: It's not something you learn to do consciously, it happens spontaneously; you only know later that it happened.

(Erickson here gives other examples of spontaneous unconscious behavior such as putting more salt on your food on a hot day without realizing it. When people, even young children, move to a warmer climate, they learn this spontaneously on an unconscious level.)

R: This again emphasizes that therapeutic trance is a state of active learning that takes place autonomously without conscious intervention.

THE SURPRISE

Erickson frequently utilizes "surprise" to shake people out of their habitual patterns of association in an effort to facilitate their natural patterns of unconscious creativity. The problem with offering direct suggestions is that unless they are carefully integrated with the patient's inner experience, they may interfere with the autonomous and creative aspect of trance experience. If trance is a focus of a few inner realities that move by themselves, then the therapist's direct suggestion may come as an intrusion on that autonomous inner flow. The direct suggestion might inadvertently activate the patient's conscious intention to try to do something on a voluntary level. By asking patients simply to "wait for a surprise," on the other hand, we are allowing them to remain in quiescence while unconscious processes gradually mobilize a truly autonomous response.

"Surprise" is an agreeable word to most people. It conjures up many associations of pleasant childhood experiences and surprise parties and gifts. The ego is usually receptive to a surprise. A surprise always implies that the subject will have no control—and that, of course, facilitates autonomous functioning. The word "surprise" is thus a conditioned cue for most people to give up control and to be curious about the pleasant thing that is going to happen to them.

E: Or would you like to have it as a surprise?

Now or later?

R: That question actually implies a pleasant experience will happen. To that surprise is added another about time.

Shortly I'm going to lift your hand in the air. What happens after that is going to surprise you.

E: When the subject goes through all the possible surprises, what can surprise them?

R: An unusual thing.

E: And what unusual thing is there? The hand could stay there and the subject cannot put it down.

You are pretty well aware of all the things you can do, but the most surprising experience you can have is to discover that you can't stand up, n ... o ... w.

R: The first part of this statement is a truism: the subject knows what she can do. The surprise about not being able to stand up comes as a shock that tends to depotentiate her usual conscious sets and facilitate the immobility of the lower body. This surprise is thus another classical example of not doing. The drawn-out emphasis on the word "n. . .o. . .w" evokes a curiosity response from the subject, who says to herself: "What does that mean? Is anything happening? What has happened?" These questions allow an opening and time for the autonomous process of immobility to develop. The typical subject then begins to move the top part of her body to test the suggestion but leaves the bottom part from the waist down immobile. Frequently the therapist can give the subject a surprise slap on the thigh so she can experience the further surprise of a caudal analgesia.

Another example of the surprise was related by Erickson as he discussed his permissive approach in allowing patients to express their own variations to a hand levitation approach.

"The therapist's attitude should be completely permissive so a patient can respond in any way to hand levitation—even by pushing down harder and harder. I'm thinking of a certain college student who did that. After he did that long enough I said, 'It's rather interesting—at least it is to me. 1 think it will be up to you when *you discover that you can't stop pushing down.'* He thought he was resisting. The idea that he couldn't stop took him completely by surprise and it was a full-grown idea when it hit him. That would be something he would be interested in. He would be surprised! He couldn't be surprised unless he couldn't stop pushing down. Not being able to stop pushing down was made contingent upon the idea of interest and a surprise. He found to his surprise that he couldn't stop pushing down and he asked, 'What happened?' I said, 'At least your arms have gone into a trance. Can you stand up?' Can he? That simple question elaborated 'At least your arms have gone into a trance,' and extended it to his feet. Of course, he couldn't stand up. There was only one conclusion to reach: his body was in a trance because he no longer had control over it. That apparently was what he wanted—to regard hypnosis as a condition in which you have no control over yourself."

The shock and surprise this student experienced must have been all the more upsetting since he obviously had a high investment in not following suggestions, as is indicated by his pushing his hand down when it was suggested that it levitate. In this case Erickson states, "Not being able to stop pushing down was made contingent upon the idea of interest and surprise." Erickson did, in fact, succeed in evoking interest, shock, and surprise with his provocative statement, "It's rather interesting—at least it is to me. I think it will be to you when *you discover that you can't stop pushing down."* He evoked a shock and surprise that momentarily suspended the student's belief system. In that precise moment he added the suggestion, "You discover that you can't stop pushing down."

Exercises with Surprise

1. Surprise has a number of possible functions in hypnotic work.

a. A shock and surprise can momentarily depotentiate an individual's habitual mental sets so that perception and understanding may be spontaneously reorganized in a new way.

b. An anticipation of a pleasant surprise has motivating properties and leaves the individual open, aware, expectant of something. That something can be either a new insight from within or an important suggestion from the therapist.

c. The anticipation of a pleasant surprise allows the ego to relax so that more autonomous processes can function in a way compatible with trance.

Plan how you could utilize the above characteristics of surprise to enhance an experience of each of the classical hypnotic phenomena.

2. To learn something about a person's fundamental world view and habitual frames of reference, ask about their most "surprising life experience." And what would be the most surprising thing that could happen to them?

3. Once you understand something about a person's world view, plan how you could say or do a simple and innocent thing that is a bit outside that world view so the person is shocked and surprised. Of course, tact and good taste are required for such adventures. With experience you can learn to elicit a double-take and a laugh from people as they spontaneously reorganize their perceptions and/or accept a suggestion you offer them at that critical moment of surprise when there is a momentary suspension of their habitual sets and patterns of understanding. This kind of approach is used by professional comedians and some skillful orators.

THE CONFUSION-RESTRUCTURING APPROACH

A major theme reiterated again and again in the most surprising contexts by Erickson is that the patient "does not know" what is happening. Of course, consciousness is at all times limited. Consciousness focuses on this or that, ever shifting from moment to moment. At any given moment it can only be focused on a limited range of information. Erickson utilizes this limitation by continually introducing changes in areas outside that momentary focus of consciousness. If he can be sure that the patient's consciousness is focused in area A, then he will introduce a change in area B. When the patient's consciousness returns to refocus on B, the patient is in for a surprise: an unexpected change has been introduced. This surprise throws off patients' usual reality sense, they become confused, and they reach for and accept any suggestions that the therapist can introduce to restructure the lost reality.

In chapter One we discussed how Erickson did not find hypersuggestibility characteristic of trance (Erickson, 1932). We can now more clearly understand what he meant. Under the shock and surprise of many of the older authoritarian approaches to hypnotic induction, it is obvious how the confusion-need-for-restructuring mechanism operated so automatically that it appeared as if the patient was hypersuggestible in trance. This so-called hypersuggestibility, however, is actually the automatic acceptance of any acceptable restructuring that will end the intolerable confusion that has been effected by the hypnotic induction or any means of unstructuring the ego's usual frames of reference.

The basic process required for the acceptance of suggestions by the confusion-restructuring approach, then, is as follows.

CONFUSION
due to shock, stress, uncertainty, etc.
↓
UNSTRUCTURING
of usual frames of reference
↓
RESTRUCTURING
needed
↓

RECEPTIVITY
to therapeutic suggestions

The reader can understand the above as intervening steps between stages two and three of the flow diagram presented in the previous chapter on Confusion in the Dynamics of Trance Induction. Acceptance of the therapist's suggestions will be in direct proportion to (1) the optimal degree of unstructuring and (2) the appropriateness of the therapist's suggestions for restructuring a particular patient in a therapeutic manner. What people can accept as restructuring is very much a function of their therapeutic needs and goals.

Erickson uses this basic method of confusion-restructuring in therapy as well as in inducing hypnosis and facilitating the acceptance of suggestions. He has described many instances where he uses shock (Rossi, 1973b)—for example, to unsettle a patient's problem so the patient will grasp therapeutic suggestions to restructure a now shaken sense of reality. A rather dramatic example of Erickson's use of confusion-restructuring in induction is in the situation where a nurse reluctantly came to the front of an audience to serve as a demonstration subject. As she approached Erickson he confused her as to which chair she should sit in by unexpectedly directing her alternately from one chair to another. (He directed her nonverbally to one chair while verbally indicating another.) When she was thoroughly perplexed, he finally said, "Go into a trance as you sit all the way down," and simultaneously indicated clearly which chair she should sit in.

Such approaches are obviously only suitable for therapists with quick wits and some practical experience. There are, however, many types of confusion-need-for-restructuring situations in everyday life and psychotherapy that can be creatively utilized by any therapist. The momentary confusion of a loud noise or unexpected event, for example, produces a momentary gap in understanding that requires an explanatory suggestion. Erickson is continually playful in the way he introduces puzzles and oddities in the therapy situation that confound the mind so it will be receptive to suggestion. He will ask someone a beguilingly simple mathematical question, or drag out some fascinating esoterica from a Believe-It-or-Not article. By such simple means he confounds the usual limiting sets of consciousness and awakens a need for explanation and restructuring. A "yes" or accepting set is established, and the patient is grateful for anything new the therapist can then introduce.

Readers will have to determine for themselves the degree to which these various levels of confusion-restructuring can be used comfortably in their own therapeutic practice. A simple awareness of the confusion-restructuring process can be of immense value regardless of how the therapist feels about purposely provoking confusion. Most patients bring in enough confusion of their own which they want therapy to resolve! Rather than viewing such confusions negatively as indicators of pathology or problems, however, the therapist can look upon them as opportunities to help patients restructure their world.

Exercises in Confusion and Restructuring

1. Surprise, confusion, and restructuring are all intimately related processes. To learn to utilize them creatively in therapy requires a certain flexibility in the therapist's world view. Creatively oriented therapists will therefore seek out life experiences that will enable them to continually break out of the limitations of his own habitual framework (Rossi, 1972b).

2. Uncertainty, ambivalence, and confusion are typical complaints of people who come to therapy. These are frequently treated as symptoms the therapist is supposed to remove. We can now understand how they are actually a preliminary stage for the possible creative change and growth of the personality (Rossi, 1972a; Rossi, 1973). Learn to recognize in these complaints the outlines of what is changing in a patient's world view and how that change can be facilitated in a growth-enhancing manner.

THERAPEUTIC TRANCE AS A STATE OF ACTIVE UNCONSCIOUS LEARNING

Erickson makes it clear that therapeutic trance is a state of active learning on an unconscious level; that is, learning without the intervention of conscious purpose and design. Trance experience may be likened to that of the dream wherein mental events usually proceed autonomously.

There may be a question here as to whether this is true learning (in the sense of an acquisition of new responses) or merely automatic behavior on an unconscious level. The proof of new learning must always lie in the results: Does the patient actually evidence new response capacities as a result of his hypnotic experience?

Erickson continually emphasizes learning without awareness. In this induction section, for example, he says to Drs. H and S, "You are developing your own psychological techniques of psychotherapy without knowing that you are developing them." He clearly believes that such learning can take place more effectively and creatively in an altered state, when many of the usual biases and preconceptions of the patient's conscious frame of reference are not active. Therapeutic trance is thus a condition wherein the usual biases and distractions of consciousness are minimized, so that new learning can take place most efficiently.

This view is entirely consistent with what is known about the creative process in general (Rossi, 1968, 1972a; Ghiselin, 1952), wherein it is recognized that consciousness is only a receiving station for the new combinations of the creative process that actually take place on an unconscious level. It is also consistent with the early hypnotherapeutic approaches of Liebeault, Bernheim, and Braid (Tinterow, 1970), who would sometimes place patients in a healing trance for a short time and then "wake" them up without any further direct suggestions about exactly how the therapy was to take place. The "healing atmosphere" provided by such early workers together with the belief system of their times functioned as indirect and nonverbal suggestions to set in motion creative, autonomous processes within their patients that could effect a "cure." Modern 20th-century man is handicapped, however, by a materialistic, and overrationalistic belief system that tends to downgrade the functioning of these autonomous therapeutic processes. Modern man has an unfortunate hubris of consciousness (Jung, 1960) wherein he believes everything mental can be accomplished on a conscious and voluntary level. Such voluntary efforts frequently get in the way of natural healing processes. To cope with these misguided conscious efforts, Erickson developed indirect approaches such as confusion and restructuring as a means of confounding patients' conscious limitations so their unconscious has an opportunity to create new solutions.

FIVE

Trance Learning By Association

In this session Erickson again uses a more accomplished subject, Mrs. L., to demonstrate hypnotic responsiveness so that Dr. S can learn by association. Erickson begins with a surprise: he asks Dr. S to perform her first hypnotic induction on another person. She does this surprisingly well in a way that is original while still utilizing a number of basic principles of hypnotic induction. The significance of this surprise request is that it prevented Dr. S from rehearsing ahead of time; it forced Dr. S to rely on her intuition and the unconscious learning she has acquired thus far in her personal experiencing of trance. Erickson encouraged her to learn to use experiential rather than intellectual knowledge.

In this session Erickson returns to the theme of unconscious learning as a basic issue in doing genuine trance work. He comments that Dr. S still "doesn't quite trust her unconscious mind to do all the learning necessary." He clearly means that during trance the patient is learning without the usual mode of ego consciousness. Consciousness is not necessary for learning. Indeed, Erickson prefers learning to take place without the biasing intervention of consciousness.

In experimental psychology it has been demonstrated that learning can indeed take place without awareness (e.g., the so-called latent learning). Such learning without awareness is Erickson's preferred way of working with patients in trance. Erickson has commented on the fact that much of what passes for hypnosis in the experimental literature, where a short induction of a few minutes' duration is followed by standardized suggestions (that do not take into account or meaningfully utilize patients' individual differences), is actually a mixture wherein the patient uses conscious volition mixed with unconscious learning. This reliance on conscious volition and direction is the mark of an inadequately trained hypnotic subject. Such subjects will quickly reach a limit in the degree to which they can experience genuine hypnotic phenomena because their conscious sets and learned limitations interfere with the efficient functioning of unconscious mechanisms.

Two indirect approaches to utilizing such unconscious mechanisms are clarified in this session: the implied directive and questions, These approaches have been developed by Erickson and others in clinical hypnosis. It will be fascinating and important to study the parameters of these approaches with more controlled laboratory studies as well as further field and clinical investigations. We are just now beginning to appreciate the complexity and vastly unrealized potential for using language to effect therapeutic goals.

In this session Erickson requested Mrs. L, an excellent hypnotherapeutic subject with whom he has worked before, to be present. In a surprise move he asks S to hypnotize L. This is the first occasion on which Erickson is able to observe work with hypnosis as an operator. S begins by addressing her suggestions to the subject.

A Successful Practice Induction

S: Close your eyes, relax, and imagine yourself in a fantasy spot which you liked very much.

(Pause)

Either by a lake or river, just some place you like.

(Pause)

You manage to get more and more relaxed. Take a deep breath and relax.

[Subject does take a deep breath at this point.]

You start feeling more and more comfortable.

(Pause)

E: "Imagine yourself in a fantasy spot," makes it very personal. "Either by a lake or a river," now introduces reality. It becomes the patient's reality when she adds "just some place you like." "Take a deep breath," is a very safe suggestion because any patient has to breathe.

R: Yes, so S is safe in going along with what Mrs. L is naturally doing.

E: And you can add any adjective you want, in this case a "deep breath." The adjective "deep" is a suggestion that is facilitated by being associated with an inevitable response: the patient will have to breathe.

R: So this was an excellent progression of suggestions that S used here:

E: Yes. But those suggestions take Mrs. L far away from this room. They take her to some specific memory, but S doesn't know which.

R: That's the problem. A really experienced operator would know exactly where the patient was being placed unless a general exploration was wanted.

Hypnotic Tautology

You'll find this world your very own world that you'll like very much.

(Pause)

Okay. Let's try a few signals, Okay?

(Pause)

Let this be the "yes" finger right here.

E: Given what goes just before, why shouldn't she like this world very much? You're not telling her to like it, you're just stating an obvious fact. The subject is not obeying like an automation. She will here simply agree that she does indeed like this place and feel S respects her.

R: So again S is doing very well here. She initiates an experience of relaxation and comfort in a place Mrs. L likes. She then announces that Mrs. L "will find this world . . . you'll like very much." This is actually a hypnotic tautology: S sets up a pleasant experience and then says it is a pleasant experience. Mrs. L, immersed as she is in the experience, however, does not recognize the tautology; she simply feels comfortable and respected as well since S is seemingly so correct in describing her inner experience.

Implication and Indirect Suggestion

[S taps Mrs. L's right forefinger.] And when you are feeling very peaceful and comfortable, you can concentrate on "yes"

and you may notice that finger float up.

O.K., you can do that now. You can concentrate on "yes."

[Pause as one of Mrs. L's fingers levitates.]

That's right.

E: "You can concentrate," is a statement of fact, it is not a command. If I say, "You can," it implies, "you can do that or something else." It is not a direct order. It is an inoffensive way of directing.

R: So whether S realizes it or not, she has been learning something in her personal hypnotic work with you: she's learned how to use implication and indirect suggestions.

Indirect Instruction

You are going to find that each time that you may want to spend a few minutes by yourself, relaxing, feeling very comfortable and serene,

that you can go back to this feeling,

you can put yourself into this world anytime that you like.

There are times when you really need this serene feeling.

(Pause)

O.K., now, anytime that you would like to come back and join us, you can just take a deep breath, stretch.

[Mrs. L awakens, stretches, reorients to her body. A general conversation takes place for about five minutes. Erickson then undertakes to hypnotize Mrs. L.

E: Yes. "Times when you really need." What times? You're naturally going to have some memories of some times. So this is her own exploration. She will explore, but S has not told her to explore.

R: So again in a very indirect and innocuous way S has sent Mrs. L on an exploratory trip.

E: Self-exploratory and yet not for the purpose of seeking names, etc., but for seeking serenity.

R: It seems that S has been learning something about the indirect approach to suggestion in her work with you.

Erickson Induction by Recapitulation

E: I would like to have you do today what you did yesterday.

[Pause. Mrs. L's six-week-old baby begins crying very loudly in the background, but Mrs. L pays no heed.]

You can make your own count from 1 to 20. Now you know that today's a change and go very deeply into a trance,

R: In this simple introductory statement you are recapitulating previous successful hypnotic work, and you're thereby reactivating associations that will facilitate your present hypnotic work.

R. Why did you talk of "change" here?

E: The baby crying out there was not present when I worked with Mrs. L previously. Therefore she had better change herself so that she could accommodate this new stimuli without being disturbed.

R: Without telling her directly that she supposed to ignore her baby today.

E: I gave her enough credit to know what I meant by "change."

R: If you had said directly, "Ignore your baby's crying," she would certainly have resisted.

E: What woman wouldn't?

"Losing Abilities" Rather than Direct Commands

and you learned the other day

how you could lose the ability

to stand up.

Now you can lose the ability to keep your right hand on your thigh

R: You don't command her, "You will not be able to stand up! 'You just emphasize a natural behavior since we all can lose the ability to stand at one time or other. It's relatively easy to lose an ability. In trance it is much easier *not to do something* rather than making all the effort to do something.

E: That's one thing people don't know about themselves. They don't know they can lose the ability to stand up. They don't know they can lose the ability to speak. Yet is happens all the time, as when they remark," I stood there like an idiot unable to say anything in that situation. I didn't know, enough to say anything!"

Suggestions as Inevitable Behavior

because no matter what you do

it will move up toward your face.

[Mrs. L's hand does begin to levitate smoothly toward her face.]

You can have the experience of being all alone

with only a voice.

My voice.

And soon you won't even know whether your eyes are open or closed.

You don't need to know.

And now your hand is stuck to your face.

(Pause)

You can go back to Columbia.

(Pause)

E: The patient's common reaction here is, "It will not move up to my face!" But they will be doing something, and "no matter what" they do they wind up touching their face. There is an ever-continuing threat. For example, "Try harder!" No matter how hard they try to keep their eyes open, you know they will close sooner or later.

R: *This is the logic of many induction suggestions: What the operator says is always a foregone conclusion.* Subjects do not realize that the resistance they are attempting is impossible, and they then attribute their failure to resist as giving in to the operator's power of suggestions.

E: Another example would be, "You don't know when you're going to change your rate of breathing."

R: Sooner or later everyone will change their breathing rate. You thereby also develop a set for "change" which is so important for therapy, and at the same time you depotentiate consciousness by saying, "You don't know."

Unconscious Knowledge

I would like you to learn

that no matter what any person believes,

your belief,

your unconscious belief,

your unconscious knowledge,

is all that counts.

(Pause)

In the course of living from infancy on,

you acquired knowledge,

but you could not keep all that knowledge in the foreground of your mind.

(Pause)

In the development of the human being

learning in the unconscious

became available in any time of need.

When you need to feel comfort, you can feel comfort.

When you have a need for relaxation,

you can have it.

R: Here again you are emphasizing the importance of the unconscious at the expense of the conscious.

E: Yes.

R: In referring to the acquisition of knowledge from infancy and the potential availability of such knowledge, you are making an effort to activate association pathways to unconscious learning and knowledge that can be utilized in dealing with current problems. You closely associate this suggestion with the ordinary ones for comfort and relaxation that have been successful with S. This association of a new suggestion with one that has been previously successful tends to facilitate the new suggestion.

Hypersuggestibility as an Artifact

And many times in the past

you have been able to hear something

and to forget it immediately.

(Pause)

It is a common experience.

When being introduced,

you shake hands and go on to the next person.

And wonder what Mrs. Jones' name is

(Pause)

while you are shaking hands with Mrs. Smith.

Your mind has that

knowledge,

and you don't even need

to know that you have it.

(Pause)

Months later you can meet Mrs. Jones on the street and spontaneously call her by her name.

You don't even need to know when or where you met,

for when the occasion arises,

your unconscious will supply that knowledge.

R: Here you begin to elicit forgetting mechanisms by leading her into association pathways where forgetting is likely to occur. This is very typical of you; you rarely give direct suggestions. In one of your early papers [1932, Possible Detrimental Effects of Experimental Hypnosis] you even say of your experience with thousands of trances that "hypersuggestibility was not noticed." Is it possible you don't believe that hypersuggestibility is characteristic of trance? You substitute the gradual elicitation of natural mental and behavioral mechanisms by verbal and nonverbal associations for the so-called phenomenon of hypersuggestibility of trance. Hypersuggestibility is actually an artifact?

E: Yes. It's just called hypersuggestibility.

R: But it's really natural mental and behavioral mechanisms the operator has succeeded in leading a patient into. The art of hypnosis is the skill with which the therapist succeeds in evoking these natural mechanisms for a specific therapeutic purpose.

The Implied Directive

As soon as you know only you and I,

or you and my voice are here,

your right hand will descend to your thigh

[Pause as her hand begins to descend]

here is only here,

nothing more.

(Pause)

You don't even need to know your name.

As you learned a long time ago

you are me,

and me was everything.

(Pause)

I would like to have you count backward from 20 to 1,

and begin the count right now.

R: This is a subtle form of directive where you don't actually tell her to do something, but you assume something will be done. You then only give her the option of signaling

when it is done. The giving of the signal when it is done actually seems to have both motivating and reinforcing properties on the implied directive.

E: A parallel with ordinary behavior is when you eat or drink until you are satisfied. *You will know* when the eating and drinking are done.

R: Do you agree that "the implied directive" is a good name for this?

E: Yes. I'm not telling her to ignore the presence of others in the room. No one can do that. But you can limit your awareness. We all have had extensive training in limiting our awareness.

R: We can limit our awareness to a book, a movie, etc. Actually that is another way of describing concentration: the mind focuses on one limited area and omits everything else.

Trance as Altered State

[Mrs. L opens her eyes but does not reorient to her body. Therefore she is still in trance.]

Tell us what you think we've experienced.

[Pause. Mrs. L's baby continues crying very loudly.]

L: We were talking and we were very comfortable.

E: Do you hear your daughter?

L: Yes.

E: How do you feel about that?

L: Comfortable.

E: Does it distress you?

L: Somewhat, but I don't want to help her right now.

E: That's an odd feeling, isn't it?

L: Yes.

E: It's a nice thing to learn

because it will teach you objectivity,

which will enable you to do right things at the right time

in the right way.

A little exercise by your daughter

is good for her.

R: Because she did not reorient to her body we know she was still in trance even though she opened her eyes.

E: The fact that she still is "comfortable" and does not want to bother helping her crying daughter also verifies the trance state. There is something lacking there in the total awareness of the self and the situation.

R: Showing that she is in an altered state.

E: An altered state, and she knows it! A person in trance doesn't feel certain things that are appropriate.

R: So this helps us to understand trance as an altered state.

E: Yes. Her verbal statement means: I know the baby should be attended to, but I don't feel like it; the momentum does not exist to lead me to the effort to attend to her.

R: In trance the motivating properties of stimuli are lost?

E: There is a limitation of what would normally be spontaneous behavior.

R: There is a limitation of the ego's executive function of relating appropriately to the outside world. They do not relate to the outside world except through the therapist.

Double Bind Question for Ratifying Trance

E: You really think you are awake, don't you?

L: No.

E: That's right, you don't.

(Pause)

R: You are affirming the trance with this double bind question? E: Yes. I'm proving the trance exists.

Negative Visual Hallucination

E: Who is here?

L: You are.

E: Who else?

L: I don't know.

E: Is your daughter's voice here?

L: Yes.

E: That's a nice sound, isn't it?

L: Yes.

E: How do you feel about being in a trance with your eyes wide open?

L: I like this better.

Because then I know what is going on.

E: And what is going on?

Are you enjoying yourself?

L: Yes.

R: Her response of not knowing who else is here is actually a negative hallucination; she is apparently unaware that S and I are seated right next to her, well within her range of vision. So here she has lost the ability to be aware of our presence, which you earlier suggested to her in the form of the implied directive.

Literalism to Evaluate Trance

E: What am I doing?

L: Talking.

E: Anything else?

L: Looking at me.

E: Anything else?

L: No.

E: And how are you seeing me?

L: With my eyes.

E: What else do you see?

L: That book.

R: The literalism of these responses ("talking," "looking at me," "with my eyes") is a classical indication of deep trance. You might appear to be having a casual conversation, but you are actually making a careful evaluation of her mental state.

Questions as Suggestions

E: Can you look and not see?

L: Yes.

E: And we can be all alone here.

(Pause)

Or someone named S can join us.

R: Posing a suggestion indirectly in the form of a question carries less risk of failure. If they cannot accomplish the suggestion they simply say "no" and nothing is lost. We don't know if she actually did experience a negative hallucination of not seeing here since you did not test it.

Indirectly Motivating Trance: Resistance and Unconscious Learning

Look at S.

Tell S to count to 20.

L: Count to 20, S.

E: And to take a deep breath at the count of 20.

L: Take a deep breath at the count of 20.

(Pause)

E: What change do you notice in her?

L: She breathes slower,

her head lowers,

her eyes are closed.

(Pause)

E: What else do you notice?

L: She is relaxed,

her hands are on her legs.

E: Do you think she knows her hands are there?

L: I don't know.

R: Why do you have Mrs. L in trance now hypnotize S?

E: I've had subjects determined not to go into a trance even though they volunteered. I let them express their resistance, and then I tell them to hypnotize someone else. When they hypnotize someone else they start wanting the hypnotic trance to develop.

R: So you've changed their set from resisting trance to wanting trance by making them an operator.

E: They now want a trance, but it's not been defined necessarily as trance in another.

R: This is an interesting example of how you indirectly enhance motivation for trance experience. At some unconscious or preverbal level an individual does not distinguish between "wanting a trance" for oneself or another. Wanting a trance for someone else will, by association, evoke partial aspects of trance in oneself and therefore enhance the possibility that one will more easily experience a trance if given an opportunity at that time. You were treating S as a resistant subject here?

E: Oh, yes. Her resistance isn't toward me or toward learning. *She just doesn't quite trust her unconscious mind to do all the learning necessary*.

R: Her conscious mind keeps coming in during her trance efforts.

E: To make sure.

R: This is a typical problem many intellectually trained professional people will have in experiencing trance and learning on an unconscious level.

Not Knowing:
Utilizing Established Learning

E: You don't need to know where your hands are.

S doesn't need to know where hers are.

(Pause)

R: Here again you use not knowing: "You don't need to know where your hands are." You don't try to directly suggest, "Have no awareness of your hands." You simply point out that she need not know where they are. This utilizes that everyday mental mechanism where we don't actually have to know where our hands are such as when we watch TV or a movie, for example.

E: When driving a car you don't always have to have your foot on the brake. You don't need your best dress today. There are a lot of don'ts in life.

R: You keep emphasizing all those "don'ts" and things you don't need; it's a means of relaxing the directing and controlling functions of the patient's ego.

E: By using established learning patterns.

R: So instead of giving direct suggestions, you use established learning patterns that are already present in the subject.

Positive Visual Hallucination

E: And in some way

I want you to see someone

who is someone between you and me

whom you haven't seen in many years.

[R was actually seated between E and S. Mrs. L opens her eyes and studies R very carefully, and then with a slightly incredulous look She begins to talk with R, who gradually assumes the role of John which she gives him.]

L: John:!

E: Who is John?

L: He is a friend from college.

E: Now speak to him.

L: Hi.

R: Hi.

L: How have you been doing?

R: Pretty good.

L: Are you still in the Air Force?

R: I left.

L: Where are you living now?

R: Where would you expect?

L: Puerto Rico?

R: Yes. [A general set of questions and answers now takes place between Mrs. L and R playing the role of John.]

R: You never did positive visual hallucinatory work with Mrs. L before. Did you know she was going to respond so well to it?

E: She is a very good subject. She is a very gentle, soft personality, simple and uncomplicated. Such a personality does not feel insecure when you offer them something.

R: You don't command or apparently even suggest: *you offer* and thus utilize her own inner needs and motivation. You've also built up your successful suggestion with her by first evoking a series of easier phenomena. You had her remain undisturbed by her crying child, lose the ability to stand, engage in hand levitation, forgetting and negative visual hallucination before you felt sure enough to attempt a positive visual hallucination. This positive hallucination may be actually more in the nature of an illusion since she is actually seeing me and distorting my image to fit the image of her friend John. Presumably the next step would be a genuine visual hallucination of seeing something out there in space without any reality props.

Doubting Questions in Depotentiating Consciousness

E: Now listen to what I say carefully and really understand what I say.

E: "Do you *really* understand?" means "distrust your conscious understanding."

R: You're throwing doubt on the conscious mind again even though you seem to be saying the opposite.

E: That's right! "Do you *really* understand!" implies a strong doubt. To say, "And you will *really* understand" means the same as "you don't really understand." It has the same meaning either way you state it, positively or negatively.

Questions Ratifying Hallucinations

Why did John just leave!

He did, you know.

L: He went back home!

E: Where was he sitting!

L: On a chair.

E: Can you look over in the direction of the place where he was sitting!

[Mrs. L now looks at the seat of the chair still occupied by R. Her looking at the seat is in marked contrast to the way she looked at his face when she was talking to him earlier when she projected John on him. Looking at the seat as she is suggests that she is now not seeing R sitting there.]

E: What kind of chair was he sitting on?

L: A green chair.

E: Tell me when you think he left.

L: A few minutes ago.

E: Was he willing to go?

L: Yes.

E: Why was he willing to go?

L: He wasn't needed anymore.

E: Did you enjoy seeing him?

L: Yes.

E: I'm emphasizing John was here. He had to be here in order to leave.

R: So you're ratifying the fact that she has just had an hallucinatory experience.

E: Yes. He can't leave unless he has been here.

R: At the same time you're telling her to make him disappear.

E: Yes. But you're making her affirm he was here.

R: You ask, "Why did John just leave?" rather than simply tell her to erase the whole experience and run the risk of her denying that it ever happened in the first place. Actually, I've notices that all questions have a hypnotic effect insofar as they fixate and focus attention. Is this why you ask so many questions?

E: The patient needs help, and he does not know where to look, so I'd better focus his looking with a question.

Utilizing Patient Motivation for Visual Hallucinations

E: Is there anyone else you would like to see

that you haven't seen for a long time?

L: Yes.

E: Who?

L: Bill

L: Bonjour

[Mrs. L begins to speak French to an hallucinated friend, Bill, who is now projected on Rossi. She now looks at Rossi's face as she speaks to him.]

R: [Playing the role of Bill] Let's speak English today.

L: No.

R: By asking this question about who *she* would like to see, you're utilizing her internal memory banks and motivation to facilitate a hallucinatory experience.

Impossible Suggestions Arouse Discomfort and Resistance

R: How come? Is it not possible for me to have learned English?

L: No.

E: Your French is rusty, L. How come this person says some English words?

L: He understands, he knows one or two words of English.

[Mrs. L frowns doubtfully and appears uneasy.]

E: Everything is fine, L.

Very, very fine.

(Pause)

I want you to feel very pleased within yourself, would you?

R: Since it did not fit her internal understanding of Bill, my suggestion that Bill could have learned English had no effect. Even though she is experiencing deep trance, an obviously impossible suggestion does not work. It arouses discomfort and resistance. Suggestions must match the patient's internal needs and patterns of learning and motivation to be effective.

E: Yes, this difficulty is a good example of that.

R: You were quick to reassure her when she showed uneasiness about the inconsistency of her friend Bill knowing English.

Indirect Age Regression

Now listen to my words

very carefully.

Listen to them very carefully and understand them.

Do you think A will propose? [A is Mrs. L's husband of many years.]

L: Yes.

E: What makes you think so?

L: He loves me.

(Pause)

[Conversation wherein an age-regressed Mrs. L describes some of her husband's feelings for her as she experienced them before they were married.]

R: You solicit her careful attention to prepare her for the subtle indirect suggestion that is to follow. By using the future tense here you imply that L's husband has not yet proposed. This reorients her to the past before she was married. So you've effected an age regression without any direct suggestion for it.

E: Yes. And here again when I say, "What makes you think so?"

Structured Amnesia

E: Close your eyes,

and shortly I am going to awaken you,

and when I awaken you,

it will seem to you as if you had just sat down and were waiting for me to begin.

Is that all right?

L: Yes.

R: By reorienting her to the time before we began trance work, you are effecting a possible amnesia for the trance work that just took place (Erickson and Rossi, 1974).

Surprise for Ratifying Trance by Counting Reversal

Now I am going to start the count

now: 20, 19, 18, 17, 16, 15, 14, 13, 12, 11, 10, 9, 8, 9, 10 11, 12, 13, 14, 15, 16, 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3,

(Pause)

2,

(Pause)

1

How do you feel?

L: Fine.

R: Why do you do this counting reversal as you're waking her up?

E: You take them by surprise. They think you've made a mistake. And then they find as you count up toward 20 they are following the instruction to go deeper and deeper into trance. You reverse it downward again, and now they know from personal experience that they were deeper. They were lighter in trance and then deeper.

R: You're proving the efficiency of counting to vary trance depth.

E: Yes. I've had patients tell me "that was an awful jerk when you reversed the count."

R: That jerk proves and ratifies the trance.

E: That's their subjective proof of trance—not mine.

Successful Posthypnotic Suggestion

E: Are you ready to begin work?

L: Okay.

E: What do you think we will do?

L: I'm not sure what we are going to do. I suppose you want me to work with Dr. R so I will have a different experience.

I don't know why the tape recorder.

E: You don't?

L: No.

E: What is S doing?

L: She looks like she's asleep.

E: Have you or I bored her that much?

L: I doubt it.

E: Is she asleep?

L: Yes.

R: The fact that L is successful in following this posthypnotic suggestion which S in part failed last session indicates that L is more accomplished in trance learning. Allowing S to witness this while she is in the trance state makes it more likely that she will do it in the future.

Direct Authoritative Help for Uncertainty

[S makes motions as if to awaken]

E: Is her sleep stopping?

E: [To S] Go far away?

S: Yes.

E: Very far away.

[S now goes deeper into a trance while Erickson engages Mrs. L and R in a casual conversation wherein it is learned that Mrs. L does not recall that she has been in a trance state. Erickson now proceeds with Mrs. L as follows.]

R: S was seemingly about to wake up here.

E: You use a direct authoritative suggestion in this situation where you see a patient in an uncertain state. When she is uncertain, you help her by taking over firmly. Just as when a child is uncertain about something, you say, "I'll tell you when to go .... *Now!"* That's the same sort of thing. That is acceptable as help since patients have a long history of having accepted help in such circumstances.

R: Direct authoritative suggestion works and helps when patients are uncertain, sitting on the fence. They are not really following a suggestion, they are just accepting a helpful push.

Ideomotor Signaling to Illustrate a Conflict Between Conscious and Unconscious

E: Have we done anything to you of which you are unaware?

L: No.

E: Are you sure now?

L: Positively.

E: Have you ever seen a dispute between the conscious and unconscious mind? Now watch your right hand.

If I have done a great deal with you this morning, your right hand will lift.

[Her hand begins to lift.]

Now, have I done a great deal with you this morning?

L: A little.

E: How much?

[Her hand begins to lift more rapidly.]

L: I don't know how to measure.

E: Do I know anything about you that I didn't know before?

L: Yes.

E: What?

L: You know that I went to Tunisia.

You know about some of my friends.

E: Could you tell me more?

L: We were just talking about it.

E: When?

L: Just a while ago.

Before I went to check the baby.

E: Can you tell me more than before?

L: I think maybe.

E: What is your hand doing?

L: Staying there.

E: What?

L: I think it is going up.

E: Why?

L: I think you did more with me than I thought.

(Pause)

E: Do you believe yourself or your hand?

L: My hand.

E: Have you forgotten what I did with you?

Consciously forgotten?

L: Yes.

E: Did you see anybody here in the office today?

L: Dr. Rossi.

E: Anybody else?

L: S.

E: Here you're teaching people by this conflict that their unconscious can do something that they did not know about. She herself is furnishing that evidence.

R: So you're proving the existence of the unconscious to her.

E: In the presence of her conscious mind. You demonstrate that the conscious can think one way and the unconscious another. You're going to have a chance to see and prove within yourself that they think differently.

R: This is a highly important experience for patients to have: a demonstration of the existence of the unconscious. They would thereby tend to become more amenable to respecting and learning to relate to their unconscious. The therapist can then use ideomotor signaling to detect and monitor any sort of psychodynamic conflict in this way. There is a great need for clinically oriented research to develop new ways of using ideomotor signaling and to evaluate its validity in different situations.

E: Just as when you demonstrate to patients their motivation about stopping smoking. You ask them to put a few coins in a large bottle every time they would have lit up. A quarter or two when they would have bought a carton. Pretty soon the people who really want to quit see all that money piling up. That further motivates them to quit and save all that money. It also proves to them that they do want to quit. That is their proof. And when they fail to pile up the coins, that also is their proof that they don't want to quit.

R: I see in this the possibility of a new therapeutic technique: Externalizing internal processes and motivations so patients can relate to their inner dynamics in a concrete and easily comprehensible way. What patients do externally with the coins can be a reflection of what they do within themselves. The coins (or whatever other external gauge you attach to internal process requiring change) function as a cognitive feedback device altering the internal dynamics.

Ideomotor signaling appears to be an especially fine way of getting an assessment of internal processes and motivations because the autonomous aspect of the ideomotor movement is so convincing to the person who is experiencing it. In this example Mrs. L actually believes the ideomotor movement of her hand more than her own conscious ideation.

Double Bind Question:
Spontaneous Induction by Evoking Previous Trance Associations

E: Anybody else?

L: John.

E: You saw him?

L: Ummm.

E: Do you know you are in a trance right now?

L: No.

E: You really can go into a trance

effectively.

You can enjoy

using your abilities

R: She was awake; why was she going back into trance about here?

E: That's a thing you have to watch for. I noticed here that her face began to iron out and that there was more of a fixed, unblinking stare and a lessening of body mobility as she talked. *Trance tends to be revivified when you review any hypnotic phenomenon that has occurred in the subjects.* They begin to relive what they are talking about and begin to reexperience the trance, sometimes with and sometimes without their knowledge. So then you say, "You don't know you are in a trance?" And they don't know. So you've just taught them it's possible to go into a trance without knowing it.

R: That's a fantastic way of circumventing consciousness. E: Yes.

R: You revivify the trance by talking of trance events. Then you slip in the double bind question, "Do you know you are in a trance right now?" An answer of "yes" means she knows, an answer of "no" means she does not *know* she was in trance. Both answers imply an acknowledgment of being in trance, only the knowledge of it was in question. This reinforces trance further, so she recognizes that trance happened without her consciousness knowing exactly why. This demonstrates how little the conscious mind really knows. That is a very important learning because it enables her to recognize the value of exploring her unconscious and its capacities, which are greater than her conscious mind believes.

E: That's right.

Facilitating Unconscious Potentials: Reinforcing Suggestions With Truisms

A process that you don't know you have

but abilities that are in your unconscious mind.

(Pause)

Your eyes are wide open

and adjusting so it won't get dark.

(Pause)

R: Here again you reinforce the idea that she has more ability than she believes. You're always building up the unconscious and the greater potentialities that people actually have while depotentiating their conscious mind with its limited beliefs about what can be accomplished. You allow a brief pause for that message to sink in, but then, before she can debate the matter, you immediately follow up with a self-evident truism about her eyes being open. The obvious truth of this must evoke a "yes" within her that may now in part reinforce the previous suggestion about her unconscious abilities. You like to use statements of obvious truth to reinforce a previous suggestion. In your interspersal technique (Erickson, 1966b) you use a series of obvious truths to surround and thus reinforce every suggestion.

Posthypnotic Suggestion as Conditional Suggestion

E: I am now going to awaken you and I want you to be very surprised

you won't be able to bend your legs

E: I'll take credit for awakening her, but she takes credit for going into trance.

R: You're using the conditional suggestion format for this posthypnotic suggestion. The suggestion ("you won't be able to bend your legs") is paired with an inevitable occurrence ("I am now going to awaken you")

Set, Mental Flux, and Creativity

and you won't, will you?

(Pause)

You will see them but you won't be able to feel them

after I awaken you.

Agreed?

20, 19, 18, 15, 12, 10, 9, 8, *5,* 3,

2,

1,

Are you ready to check on your daughter now?

L: No

(Pause)

E: How do you really feel?

(Pause)

E: These shifts from the negative (won't) to the positive (will) and sometimes the shifts from positive to negative are keeping the patient in a constant state of movement. You change the mind this way and back.

R: What's the value of keeping that constant movement?

E: You don't let the patients get a set. A mental set they can stay with.

R: Why not?

E: You don't want them with *their* mental set.

R: You keep them in movement so they will have to grasp onto your mental set?

E: Yes, the mental set you want to work with. You keep them in flux so you can constantly orient them. But you aren't telling them, "I want you to pay attention to this one thing."

Not Doing:
Generalizing Successful Posthypnotic Suggestion

L: My legs aren't awake.

They don't work.

E: How does that make you feel?

L: Awkward.

E: How does that make you feel when your legs don't work?

•L: Very limited.

E: It doesn't distress you, does it?

(Pause)

E: And you can do that with any part of your body any time it is necessary.

You can also use them any time it is necessary.

Any time you need to you will be in full possession of your abilities. Do you understand that?

E: She has a master's degree and yet she uses this juvenile language here. Hypnotic subjects do regress to simpler forms of thinking, feeling, and behavior. Simpler, more youthful, less complicated forms.

R: There is even more to this posthypnotic suggestion of not being able to stand: you are emphasizing *not doing* as a basic mode of hypnotic experience. You are giving her an experience in the basic notion that in trance it is not the ego or the patient's usual waking patterns that accomplish the hypnotic suggestion. In your paper on deep

hypnosis (Erickson, 1952) you said, *"Deep hypnosis is that level of hypnosis that permits the subject to function adequately and directly at an unconscious level of awareness without interference by the conscious mind". In* a simple and subtle way you then generalize this successful posthypnotic suggestion on her legs to include any other part of her body. You can greatly expand the area of any successful suggestion by this simple phenomenon of *generalization.* It's a basic principle of learning theory as well as hypnosis.

Posthypnotic Suggestion and the Reinduction of Trance

Do you think you are wide awake?

L: No.

E: That's right.

Close your eyes, and now this time you can awaken when I say, "one."

Now, one.

R: She is still in a trance because she is now carrying out your earlier posthypnotic suggestion, "You won't be able to bend your legs." You have described (Erickson and Erickson, 1941) how carrying out a posthypnotic suggestion reinduces a momentary trance that can be utilized to reestablish another trance. This illustrates the care one must occasionally take to awaken a subject when posthypnotic suggestions are used. You noticed at this point that even though you went through a formal "awakening" procedure by counting backward to one, she did not go through the typical awakening movements of stretching and so on to reorient to her body. Therefore, she may not be really awake. This is confirmed when she acknowledges the posthypnotic suggestion with her statement about her legs not being awake. You therefore ask the double bind question about whether she "thinks" she is awake. Any answer (yes or no) can imply she is still in trance. She readily admits she is still in trance, so you simply go about reawakening her again

[L now reorients to her body by moving her hands a bit, readjusting her legs, etc.]

Ratifying Awakening and Trance: Ideomotor Movements and Dissociation

What is the different feeling you have now? (Pause)

L: I can do what I want, what my conscious mind is thinking about. Before, I could think about things but I didn't really feel like doing anything about it.

E: That's right.

Anything else you would like to add?

L: Well, when I am in a trance, I am much more relaxed, feeling, sort of good,

except when I'm in a really deep trance,

like I tend to lose the sense of balance a lot and I feel slightly awkward.

R: Are you confirming she is now awake as well as ratifying the trance by asking her what different feelings she has on awakening?

E: Yes. When you think about things, your body makes many ideomotor movements. When children watch a movie, it's particularly obvious how they move about, thrusting this way and that, acting out the scene they are watching. Here Mrs. L is saying, "I can do what I want, what my conscious mind is thinking about. In trance I could think about

things but I really didn't feel like doing anything about." In ordinary waking state you start thinking about scratching your head and you immediately get subliminal movements in your fingers to do it. But in trance you can think about it without subliminal movements.

R: In the ordinary waking state ideomotor movements are acted out, in trance they are not?

E: Yes.

R: But how about finger signaling and hand levitation where you are using ideomotor movements to initiate or deepen trance?

E: That is where the operator is using ideomotor movements in a special fashion. You see a child watching a movie go through all the actions of what he is watching. But if you put him in a trance to hallucinate the same movie, he will watch it without body movements. He just sees.

R: So there is a dissociation between ideation and that motor behavior in trance. That's why people are so quiet in trance. And that body stillness can be taken as a reliable indicator of trance.

E: Yes.

Facilitating Creativity, Enhancement of Abilities

E: It's allright to feel that way, but you don't have to be off balance.

You can feel any way you want to, but you don't have to be any way that you don't want to be.

It is nice to feel warm when you are cold.

It is nice to be cold when you are warm.

How is it when you feel wet all over?

L: It makes me feel dry.

E: Describe that feeling for me.

E: If she can't think about walking and do it in the ordinary way (in the awake state), she loses her balance. (Erickson demonstrates how he cannot really think about moving his paralyzed right arm without moving his left arm, which is not paralyzed.) I can't get any minimal movements in the right hand, so I can't even feel how I would move it if I could. Body feelings complement the thought of lifting the hand.

Now Mrs. L has lost her sense of balance because she lost her body feeling in trance.

R: She lost the sensory feedback the muscles give the mind, so she loses her sense of balance.

E: That's right! But if you instruct the person to have those movements, he can. When training a rifle team, I saw to it that they had certain types of subliminal body movements that were conductive to accurate shooting. When a shot-putter got stuck on the shot-put at 58 feet, I pointed out that his muscles did not know the difference between 58 feet and 58 feet and one-sixteenth of an inch. Roger Bannister broke the four-minute mile by reducing four minutes to 240 seconds because here 1/1000 of a second counts.

R: This is all due to altering body feedback, altering the ideomotor connections. So you can actually enhance physical abilities by breaking through conscious bias about limitations.

E: Yes, unrecognized conscious bias.

R: Perhaps this is the secret of enhancing abilities in hypnosis: breaking through the conscious bias of what our limitations are.

E: Yes. People say, "But I always eat cereal for breakfast! But we always have chicken on Sunday." These are all conscious biases. You can broaden your activity, however, if you recognize the bias. Experimentalists in hypnosis ought to know about the unlimited number of biases that everybody builds up.

R: These biases are bedeviling their experiments, they are part of the source of individual differences, etc.

E: People who accomplish a great many things are people who have freed themselves from biases. These are the creative people.

R: You can define creativity as freedom from the biases of the past. If you can break out of the sets of your forefathers, you can experience originality.

E: It's simply a conscious bias when people say they don't like cold. Sometimes it's good to feel cold—especially when you're too warm.

R: So you're breaking through her conscious biases here and making her a more flexible person with these instructions. Then she picks up your idea of flexibility when she answers, "It makes me feel dry," to your query about wet.

E: Yes.

Induction of Trance by Removing Common Sets and Biases

L: It's kind of cold—no, I'm comfortable, but cold.

E: All right.

You can be dry now.

Now I am going to do something.

(Pause)

I want you to have a certain feeling

and a contrary knowledge.

I want you to feel naked from the waist up

even though you know

You are dressed from the waist up.

I want you to feel naked.

(Pause)

R: She has been awake up to this point, but now she's going back into trance in a seemingly spontaneous manner here since she says "I'm comfortable." Why?

E: Because I have removed biases.

R: Really? You have removed biases and conscious sets so she automatically slips into trance?

E: Biases are a part of our conscious living.

R: They keep us conscious? Would you go as far as that?

E: They are not just biases, they are part of the way we experience the world.

R: They are so much a part of the ground of our everyday experience that if we are deprived of them, we suddenly lose our conscious orientation. And that results in trance. So by simply removing people's biases and preconceptions, they tend to go into trance. I find that so hard to believe!

E: You have given them a new kind of freedom in the trance state. With a few simple words you restore a sense of freedom, and that belongs to the trance state. They then begin to feel that freedom.

R: Freedom from conscious bias is characteristic of the trance state. Can we then call this an indirect reinduction of trance by removing biases?

E: When you use the word "bias" it is so easily misunderstood. It is actually a *common set.*

R: Removing a common set is what reinduces trance?

E: Yes. Another example is that when you have a subject talk about trance events and feelings, he slips back into trance. That's what Jay Haley means when he says I take a person in and out of trance without awareness of it.

Questions to Ratify Hypnotic Phenomena: The Implied Directive

Do you want R to look at you?

L: No.

[Mrs. L now covers her breasts with her arms crossed over them.]

Do you want me to look at you?

L: No.

E: To answer that question she has got to feel naked.

R: So you are ratifying the hypnotic phenomenon of feeling naked. That's another example of the *implied directive* by asking a question that requires a hypnotic experience to have occurred!

E: That's right!

R: You know these things are so subtle that I actually feel a bit dizzy, a bit not quite all here, in my effort to understand these things. I feel as if I'm in hypnosis right now. It's so hard to understand these things. I guess my old mental sets are breaking and my effort to grasp this new understanding makes me feel a little woozy!

E: She covers her breasts with her arms here. So I dodge all the difficulties of directing her to being nude by simply asking that question.

R: You dodge all the doubts she might have had about whether or not she really felt naked, etc.

E: I made it a *fait accompli* by asking that question.

R: You use that *fait accompli* a lot by the careful use of questions.

E: That's right.

Contradictions: Conscious and Unconscious

E: There is a contradiction, isn't there?

L: I guess so.

E: It makes you uncomfortable, doesn't it?

L: Yes.

E: It is a delightful thing to be able to use your mind consciously

(Pause)

and unconsciously.

[A few personal and identifying sentences are omitted here.]

E: What is the contradiction? She is getting nude for me (obeying the hypnotic suggestion), but she doesn't want me to look at her. She doesn't really get what I mean when she answers, "I guess so."

R: Since she doesn't understand, you're again keeping her off balance.

E: I also discharge any great, discomfort by letting her know it's "delightful" to be contradictory insofar as you're able "to use your mind consciously and unconsciously" while it allows her to continue to be nude.

R: You let her be comfortable with the contradiction and at the same time reinforce her being nude. You have her all tied up, she cannot move any which way but what you suggest.

E: The pause between "consciously and unconsciously" effects a separation between conscious and unconscious. It's delightful to use the conscious mind: to know you are naked. You used your unconscious mind to become naked.

R: So you let consciousness do something and unconsciousness do something, and they both cooperate in the task you're assigning.

E: That's right. She wants to be clothed. That's a conscious thing. She puts her arms over her breasts: that's a conscious thing. But she is nude: that nude feeling is from her unconscious, she got nude unconsciously.

R: She got nude unconsciously through a feeling process rather than figuring it out with conscious logic. Feelings come from our unconscious.

E: Yes.

Breaking Through Self-Limitations: Early Memory Recall

E: R would like to do something

which involves some rather complicated mental phenomena.

Are you willing to do that?

L: Okay, except I don't have a good memory of my childhood.

E: I'm glad you said that.

R: You're careful to get her permission here and give her a preparatory set for new work. I notice you always do this when you introduce something new. L, in a manner that is all too typical, gives expression to one of the ways her conscious bias limits her ability to remember. You seize upon that self-limitation and seek to break through it.

Ideomotor Signaling to Facilitate Unconscious Potentials: Depotentating the Limiting Sets of Consciousness

If your unconscious thinks you have a far better memory of your childhood than you think,

[Mrs. L's hand does lift.]

E: You have a better memory of your childhood than you know about.

Do you mind looking back at your childhood?

E: L, close your eyes.

(Pause)

I would like to have you be puzzled by

something

that you can see.

I need some information first.

Did your father have a garden when you were very young?

L: Yes.

E: All right.

I would like to have you be puzzled by something that you can see on the other side of a garden.

(Pause)

It's a little girl.

She is a nice little girl.

Maybe she is doing something she shouldn't be doing,

maybe she has dirty hands

or a dirty face.

I would like to have you clutch that child,

hold her and hold her.

> R: Her hand lifting demonstrates the difference between her conscious and limited view of herself and her unconscious's vaster degree of potentiality. In an indirect way you are also depotentiating her conscious sets and assumptions by making a contradiction evident: a contradiction between her consciously expressed opinion and her arm levitation that implies a contrary opinion from the unconscious. Again you are demonstrating how to precipitate a contradiction or conflict between conscious and unconscious to keep patients off balance, in a state of creative flux, where they are more able to shake free of their limiting sets to do more creative work with themselves. Your suggestions that she be "puzzled" introduces a set for *confusion* that also will help her break through her conscious limitations.

Generalizing Suggestions Evoking Specific and Personal Memories

I would like to have you watch her grow up.

(Pause)

And really watch that child grow up

(Pause)

and notice the changes in her.

There are going to be many changes,

many conflicting ideas,

believing, unbelieving,

some things that can't be shared with strangers,

and I want that little girl to grow up,

and after a while you will notice

that that little girl is really L.

So be interested in watching L.

(Pause)

Look at her with interest and appreciation,

and you can know anything

you wish about her,

but you will only tell those things to me that you can share with strangers.

R: You now embark on a series of very general suggestions that could apply to anyone, yet they evoke highly specific and personal memories.

E: In real life, as one grows up through puberty, one naturally goes through periods of great uncertainty: believing and unbelieving. "Some things that can't be shared with strangers" guides her into very personal feelings and experiences without my telling her to have a personal experience.

Trance Depth: Unconscious Drifting Versus the Observer Function

Notice at times you forget that girl is L

(Pause)

and then you suddenly realize yes, it is.

(Pause)

R: This type of forgetting is a means of depotentiating consciousness further in trance. She is encouraged to drift along on more autonomous and unconscious fantasy currents until she again catches herself, until the observer function of the ego again checks in, as it inevitably will. I wonder if this natural alternation between unconscious drifting versus observing and in part controlling is responsible for the alternation in trance depth that takes place spontaneously in hypnosis?

The Puberty Program

Notice that she is getting a different feeling about her body.

(Pause)

Notice that at times

that girl thinks to herself,

Is this really me?

Notice that at times you look at that girl

you can see yourself,

that really isn't me,

but yes, it is, but it isn't, but it is.

Have a very delightful time

(Pause)

E: When a girl begins to develop breasts or pubic hair, she goes through such feeling: It is me but it isn't.

R: So without her being aware of it, you're guiding her into a reexperiencing of puberty feelings.

Time Distortion in Life Review

and time is so long,

(Pause)

no matter how short the watch says time is,

it is really long. (Pause)

And since

you are going to share some of that knowledge with me,

and pick out certain definite things

that you can share with strangers,

but only those

that can be shared with strangers.

(Pause)

You have seen movies

of flowers opening

and in the same way you look at that little girl

growing up

from a little bud till full-bloom rose.

R: This is an example of your routine use of time distortion interpolated in a place where it will obviously facilitate the work at hand. You then protect her by emphasizing that she will share only certain things she can share with strangers.

E: There is another indirect association to puberty: womanhood opening up like a flower.

Awakening that Reinforces Inner Work: The Implied Directive and Posthypnotic Suggestions

And when you have completed, really

looking at her, you will awaken

and tell us only those things that you are willing to share.

[After a minute or so L awakens and stretches her arms.]

E: Hi, L.

L: Hi.

R: It's interesting how you make awakening contingent upon completing that inner task. That's a form of the *implied directive* that includes a posthypnotic suggestion to tell only what she is willing to share.

E: That's right.

R: You know she's going to have to awaken sometime, and she might even be eager to awake . She will thus do the inner work so she can wake up. When she finally does actually awaken, that tends to reinforce the fact that inner work has been done.

E: Yes, it's her admission that the inner work has been done. Awakening her in this manner compels her to do it, but I haven't verbally said, "Now you do that!" She does not recognize that I have compelled her.

Trance Termination and Amnesia

[As L awakens, Erickson greets her with a cheery "Hi" and then encourages her to recount some of her early experiences that she recovered while in the trance state. After about 10 minutes of this casual recounting, S, who had been in a trance of her own, spontaneously awakens herself. On questioning, it is learned that S felt a little bit bored, perhaps a bit resentful that L had been getting all the attention, and she just felt like awakening to join us. She had awakened herself by saying silently to herself, "I am going to count to three and then awaken feeling refreshed and alert," and she did exactly that. She is much too polite to complain to Erickson, but she is in a quietly doubtful and questioning mood about the whole procedure.

E: This cheery "Hi" on awakening is because "Hi" belongs to the world of consciousness. I'm thereby telling her to be wide awake and forget all about that unconscious activity.

R: By so dismissing it you're effecting an amnesia except for those things you said she could share.

E: Yes, I'm causing an amnesia by implying "that's all over and done with. Now let's go on to something else."

THE IMPLIED DIRECTIVE

The "implied directive" is a label we are proposing for a fairly common type of indirect suggestion that is in current use in clinical hypnosis (Cheek and LeCron, 1968). The implied directive usually has three parts: (1) a time-binding introduction, (2) the implied (or assumed) suggestion, and (3) a behavioral response to signal when the implied suggestion has been accomplished. We may thus analyze an implied directive from this session as follows:

As soon as you know

(1) A time binding introduction that focuses the patient on the suggestion to follow

only you or I, or only you and my voice are here

(2) The implied (or assumed) suggestion

your right hand will descend to your thigh.

(3) The behavioral response signaling that the suggestion has been accomplished.

An implied directive frequently used by Rossi to end a hypnotherapeutic session is as follows:

As soon as your unconscious knows

(1) A time-binding introduction that facilitates dissociation and reliance on the unconscious.

it can again return to this state comfortably and easily to do constructive work the next time we are together,

(2) The implied suggestion for easy reentry to trance phrased in a therapeutically motivating manner.

you will find yourself awakening feeling refreshed and alert

(3) The behavioral response signaling that the above suggestion has been accomplished.

When the behavioral response signaling the accomplishment is an inevitable response that the patient wants to happen (as in the above examples), we have a situation where the behavioral response also has motivating properties for the accomplishment of the suggestion. The behavioral response signaling the accomplishment of the suggestion takes place on an involuntary or unconscious level. Thus the unconscious that carries out the suggestion also signals when it is accomplished.

The implied directive engenders a covert state of internal learning. It is covert because no one can tell it is occurring since it is a series of responses taking place entirely within the subject, frequently without conscious awareness and usually not remembered after trance. Therapist and patient only know it is completed when the requested automatic response (e.g., finger signaling, head nodding, awakening from trance) takes place, signaling the end of the internal state of learning.

The implied directive is thus a way of facilitating an intense state of internal learning or problem solving. We may suppose that all of a subject's available mental resources (e.g., stored memories, sensory and verbal associational patterns, various forms of previous learning, etc.) are marshalled toward a creative state of learning and problem solving. Since recent experiments in the neurophysiology of learning suggest that new proteins are actually synthesized in the appropriate brain cells during learning (Rossi, 1973a), we may speculate that the implied directive facilitates the internal synthesis of new protein structures that could function as the biological basis of new behavior and phenomenological experience in the patient.

The implied directive is particularly interesting because of its similarity to the technique of biofeedback. In most forms of biofeedback an electronic device is used to signal when an internal response has been accomplished. With the implied directive the patient's own overt and autonomous behavioral response is used to signal when the internal response has been accomplished. The formal similarities between them may be listed as follows:

1. Consciousness is given a task it does not know how to accomplish by itself.

Raise (or lower) your blood pressure 10 points.

Warm your right hand and cool your left.
Increase the alpha of your right cortex.
Decrease the muscle tension in your forehead.

2. Consciousness is given a signal enabling it to recognize when any behavior changes are being made in the desired direction of response. In biofeedback this is accomplished by an electronic transducer that measures the response (blood pressure, body temperature, alpha waves, or muscle tension in the above examples) and makes any change in this response evident on a meter that allows the subjects to monitor their own behavior.
In the implied directive, by contrast, the patient's own unconscious system serves as the transducer indicating when the desired internal response (blood pressure change, body

temperature, etc.) has been made and translates it into an overt behavior signal that consciousness can recognize.

The advantages of the implied directive over biofeedback are obvious. The latter is a fairly cumbersome technique that requires sophisticated and expensive electronic equipment. It is limited to those responses that can actually be measured. By contrast, the implied directive requires no equipment and is limited only by the ingenuity and imagination of both therapist and patient. Although no comparative studies have been made as yet, one might expect that the electronic equipment of biofeedback might ensure a greater reliability of control than is possible with the implied directive. For this, indeed, is the major problem in utilizing any method of hypnosis: the relative reliability of response between different individuals and within the same individual on different occasions. It may well be that this reliability problem can be dealt with in part by utilizing this analogy with biofeedback. The reliability of biofeedback is due to the reliability of the signaling system provided by the electronic instrumentation. Hypnotic procedures can be made more reliable by having patients remember and report experiential and behavioral changes that initiate or accompany the desired hypnotic response. These changes may then function as signals to reinstate the hypnotic response on another occasion. In this case hypnosis and biofeedback share another common aim: to establish a connection between a conscious thought or behavior and a previously nonvoluntary response.

Exercises with the Implied Directive

1. The implied directive has evolved in clinical practice, but there is no research data that has experimentally validated its usefulness. Can the reader devise implied directives that can be validated experimentally in a controlled and objectively repeatable manner?

2. Devise implied directives that will facilitate the experience of all the major hypnotic phenomenon.

3. Devise implied directives that will facilitate the internal learning of therapeutically useful goals (e.g., freeing the unconscious from the limitations of a particular patient's ego programming to find a new solution for a problem).

4. Since the implied directive includes an involuntary signal that a suggestion has been accomplished, it can be used in place of "challenges" to test the effectiveness of trance work. In the older, classical approaches to trance training the operators "tested" and "proved" the depth and validity of trance and the strength of their suggestions by "challenging" subjects to try to open their eyes or unclasp their hands when they had been given suggestions that they could not do so. If the subjects were not able to open their eyes, then they passed the challenge and the validity of trance was established. The implied directive accomplishes the same purposes in a much more constructive and permissive manner. It leaves the locus of control within the patient, where it belongs, rather than fostering the illusion of the therapist's control. It is thus a valuable indicator for both subject and therapist that a desired response is indeed taking place. The therapist can now learn to devise implied directives as indicators of any stage in the development and accomplishment of suggestions requiring internal responses (memories, feelings, sensations, etc.) not otherwise open to the therapist's observation.

QUESTIONS THAT FOCUS, SUGGEST AND REINFORCE

One of the most surprising aspects of approach is his use of questions to focus attention, to suggest indirectly, and to reinforce all at the same time. Questions seem so innocent in everyday life. When other people question us, it is frequently from their own need, and the question implies that we know something and are quite fine to be helping them. Questions asking for help, directions, advice, and so on are all of this category and are most useful for focusing attention.

Another useful category of questions concerns abilities: Can we do such and such? This ability question frequently has strongly motivating properties from many years of effort in childhood, adolescence, and young adulthood to meet a developmental challenge successfully: "I'll try, and I bet I can!" These ability questions are therefore useful in motivating patients provided they are not overwhelming in their demand. We must take care because questions can also be piercing and destructive, as when they are experienced as the merciless stings of an examination situation or inquisition.

Recent research (Sternberg, 1975; Shevrin, 1975) indicates that when questioned, the human brain continues an exhaustive search throughout its entire memory system on an unconscious level even after it has found an answer that is satisfactory on a conscious level. The mind apparently scans 30 items per second even when the person is unaware that the search is continuing to take place. The results of such searches on an unconscious level are evident from many familiar experiences of everyday life. How often do we forget a name or an item only to have it pop up all by itself only a few moments later, after our conscious mind has gone onto something else? How often are we consciously satisfied with a solution only to have fresh doubts and perhaps a better answer come up autonomously a short while later?

The fact that such unconscious search and cognition are carried out in response to questions even after the conscious mind is apparently satisfied and otherwise occupied is a verification of Erickson's early research supporting the then controversial view that the mind could be simultaneously active on two entirely separate and independent tasks— one on a conscious level and another on an unconscious level (Erickson, 1938; 1941). This activation of unconscious resources is the very essence of the indirect approach, wherein we seek to activate and utilize a patient's unrecognized potentials to evoke hypnotic phenomena and therapeutic responses.

As usual demonstrates and indirect approach even in his use of questions, which typically structure the patient's internal associations by implication. Questions are frequently implied directives. They are often used to depotentiate conscious sets so the patient will be more open to new response possibilities. Let us analyze a few examples of Erickson's questions. It will be found that it is almost impossible to neatly classify these questions because even the simplest are very complex in their implications and effects.

Which hand is lighter?

> *Focuses* attention on hands. *Indirectly suggests* one will be lighter and may levitate. *Reinforces* lightness and possible levitation as an adequate response. It is an *implied directive* insofar as it requires a hypnotic response to be answered adequately. *Illusory choice* and *double bind* are also operative because one is being bound into making a hypnotic response whichever hand feels lightest. This question indirectly *depotentiates consciousness* because it is no unusual that the "normal" and habitual frameworks of ego consciousness cannot cope with it, so the patient must wait for an unconscious or autonomous response.

Why did John just leave?

> This question in the context of this session where Mrs. L was hallucinating John serves primarily as an *indirect suggestion* to cease hallucinating. It works by *implication* and *refocuses* attention.

Do you want Dr. Rossi to look at you?

> In the context of this session where Mrs. L is hallucinating herself as naked from the waist up, this question strongly *ratifies* the hallucinatory experience with an *implied directive* that she show some response to being naked in front of a relative stranger (she covered her breasts with her arms).

Do you enjoy

(pause)

not knowing where you are?

This is an *indirect, compound suggestion* that gains its potency from many sources. It is compound because it asks two questions at the same time: Do you enjoy? You do not know where you are? It is so difficult to answer such a double question that the patient would frequently rather just go along with it and "enjoy not knowing where he is." The use of the negative *"not* knowing" is a further source of *confusion* that is frequently too difficult to figure out, so the patient goes along. "Do you *enjoy"* indirectly suggests pleasure and is thus reinforcing.

It is evident from these analyses that we are only beginning to make a beginning in our understanding of language in general and questions in particular. The hypnotherapist would do well to make as thorough as possible a study of that branch of semiotics known as pragmatics, the relation between signs and the users of signs (Morris, 1938; Watzlawick, Beavin, and Jackson, 1967; Watzlawick Weakland, and Fisch, 1974).

Exercises with Questions for Analysis

1. Perform a similar analysis on the following questions as well as all others you find interesting in the inductions of this volume.

Would you like to enter trance now or later?
Where does your body experience its greatest comfort?
Can you say, "something?" (Note the use of this question as a test of literalism.)
Do you really understand? (The vocal emphasis is on "really.")
Can you enjoy relaxing and not having to remember?
Can your unconscious deal with that problem?
Do you feel comfortable not knowing who I am?

QUESTIONS FOR INDIRECT TRANCE INDUCTION

One of the most useful forms of suggestion is the question that (1) fixes and focuses attention while (2) helping subjects to reach into their own associative matrix to uncover useful responses that (3) can be structured into new behavior patterns. Erickson frequently induces trance and carries out an entire hypnotherapeutic session with a series of questions.

1. **What kind of trance would you like to experience?**
2. **How long will it take you to go into that trance?**
3. **How will you know you are beginning to experience trance?**
4. **Now do you really think you are still fully awake?**
5. **How much of a trance do you feel you are in already?**
6. **How soon will your trance deepen?**
7. **You will let me know when it is deep enough, will you not?**
8. **What would you now like to experience in this trance as it continues to deepen? Or would you like it as a surprise? Sooner or later?**
9. **Will you let your hand (finger, head) move when it feels warm (cold, numb, etc.)?**
10. **And you don't know how much of that numbness you would like to maintain after you awaken, do you?**

Each of these questions evokes associative responses to different aspects of trance experience within the patient. The effect of the first three is to reintegrate previous trance experiences as well as heightening patients motivation for their current experience. Questions 4 and 5 help patients assess their current status and help make the transition from awakedness to trance. Questions 6 and 7 complete this transition and set up a signaling system so that patients can let the therapist know when a trance of sufficient depth has been

achieved. Questions 8, 9, and 10 are all variations that can be used to explore the evocation of virtually any hypnotic phenomena or posthypnotic response. Questions are thus a fail-safe approach to trance experience. The question, more than any other hypnotic form, appears automatically to evoke partial aspects of the phenomena in question so that they may be expresses as a possible hypnotic response.

THE FRAGMENTARY DEVELOPMENT OF TRANCE

We feel it is better to induce a trance by fragments than by demanding the whole all at once. The questioning approach allows patients to experience trance by degrees. It also allows the therapist to continually monitor the process and know where the patient is all the time. It is similar but not identical with Vogt's fractionation technique (Weitzenhoffer, 1957; Kroger, 1963) and the process "heteroactive hyper-suggestibility" (Hull, 1933) whereby following one suggestion tends to increase the probability of following another.

R: Why is it better to induce a trance by fragments?

E: You induce a small fragment of the trance and then another. Then you can connect those two.

R: Different fragments of trance are developed by questions that function as waking suggestions? Each waking suggestion that is accepted adds another fragment of trance?

E: Yes, and then you relate them together. First you develop a catalepsy of the arm. Then you add: "And the numbness, do you notice that? "And you can't move your eyes from your hand? "All you can see is your hand? "And all unimportant sounds have dropped out?"

R: These questions successively build the trance by adding a possible experience of analgesia or anesthesia, immobility of the eyes and head and a negative visual and auditory hallucination for unimportant background details.

Exercises Utilizing Questions as Suggestions

1. Write out a complete induction using only question for the following approaches to trance:

a. Hand levitation
b. Eye fixation
c. Relaxation
d. Any other favorite approach such as visualization, etc.

2. Formulate series of questions that will focus a subject's attention and associative processes in such a manner that an experience of each of the classical hypnotic phenomena will be facilitated.

3. Formulate a series of questions that will focus a patient's memories and associations in a manner that will facilitate a therapeutic response.

4. The question approach to trance induction is very similar to the introspective approaches that are utilized in many diverse schools of psychotherapy. The active imagination of C. G. Jung (Jung, 1963; Rossi, 1972), the meditation methods of Assagioli's psychosynthesis (Assagioli, 1965), and the dialogues of the gestalt approach (Perles, 1969) all focus the individual's attention on inner realities. Thus, they are trance inducing, even though their originators usually do not recognize it. Such methods may be considered indirect approaches to trance even though they are not labeled as hypnosis. The essential identity between periods of introspection and trance was demonstrated by Erickson in his early research with Clark L. Hull (Erickson, 1964), when he found that groups of subjects asked to perform a task in introspection underwent behavioral and subjective experiences that were similar to those they had when they went through a classical hypnotic induction.

It would be instructive to the beginner in hypnosis to give subjects tasks in introspection and imagination and then ask for their subjective comparisons of these inner experiences with those of a classical hypnotic induction. What similarities are noted in their outer behavior? The relation between such introspection-imagination approaches to trance and imagination (Sheehan, 1972) are the subject of much current research (Hilgard, 1970).

DEPOTENTIATING CONSCIOUS MENTAL SETS: CONFUSION, MENTAL FLUX, AND CREATIVITY

R: You keep patients constantly in flux, slightly off balance, so they will continually grasp onto whatever orientation you provide?

E: Yes.

R: That is one of the creative states within hypnosis; that state of constant flux wherein the patient grasps the orientations you provide.

E: That's right.

R: This is in contrast to the situation where you allow patients to remain quiet by themselves in a trance (Erickson, 1955) to work out their own solution to a problem in their own way.

E: When a person goes into a trance, you bounce him around and keep him whirling and then you tell him to work quietly on that problem. You have first detached him from his conscious mental sets. You have broken the connections that might have been stopping him from working on his problem. That is a very important thing.

R: You break their habitual mental sets and the conscious biases that prevented them from solving a problem and then orient them toward creative inner work.

E: People always have that tendency to put off working on a problem to tomorrow. But you make tomorrow today by breaking those conscious sets and keeping them in a state of flux.

R: That is part and parcel of the confusion and the surprise techniques as well. All these approaches depotentiate the limitations of conscious sets.

In this conversation Erickson clearly expresses a major aspect of his work in facilitating problem solving and creativity. Earlier in the third session we saw that a flow diagram of trance induction went as follows:

DIMMING OF OUTER REALITY
↓
CONFUSION
↓
RECEPTIVITY TO CLARIFYING SUGGESTIONS
↓
TRANCE WORK PROPER

In this section Erickson elaborates further on the significance of confusion. Confusion ("you bounce him around and keep him whirling") is used to detach people from their "conscious mental sets." You have broken the connections that might have been stopping them from working on their problem. A patient is a patient because of erroneous mental sets and limited frames of reference. Erickson continually seeks to break through these rigid limitations to initiate a state of mental flux that may release the patient's creative potential.

Thus, confusion becomes a major tool for breaking rigid mental sets and initiating a creative process. An entirely spontaneous example of this process occurred in the commentary of this session, where Rossi admits to feeling "woozy" trying to break through his own mental limitations to understand what Erickson was trying to teach. This feeling actually occurred many times. The breaking of Rossi's habitual frames of reference together with the complexity which which Erickson expresses himself was sometimes enough to induce a hypnotic atmosphere. The complexity of Erickson's thought, it should be noted, was

not due to its abstract nature, but to his habitual use of indirection, questions, and implications that continually turn over a listener's associative processes in ways that are experienced as unusual and perhaps not self-directed (and therefore hypnotic).

Many of the verbal forms that Erickson uses to initiate confusion to break through a patient's erroneous conscious sets are already familiar to us: the use of provocative questions, implications, double binds, the surprise, not doing and not knowing.

At the simplest level Erickson softly and insistently reiterates all the things a patient does not need to do or know. He is actually telling the patient's consciousness that it can relinquish its usual control and direction and permit unconscious and autonomous processes to take over. The whole process of trance induction is designed to relax these habitual sets of consciousness. The trance deepens, and patients are able to break out of the learned limitations of their usual mode of consciousness to the degree that they give up what they know.

Not Knowing, Not Doing

You don't need to listen, your unconscious can respond on its own.

You don't need to know [whatever] for when the occasion arises, your unconscious will supply that knowledge.

You don't know when you are going to change your rate of breathing [or whatever].

[To a restless patient] You don't know exactly when you will feel a need to move again.

You don't need to know where your hands [or whatever] are.

I would like you to learn
that no matter what any person believes,
your belief,
your unconscious belief, your unconscious knowledge,
is all that counts.

In the course of
living from infancy on,
you acquired knowledge,
but you could not keep all
that knowledge in the foreground
of your mind.

Note from the induction section how these last two suggestions lead up to Erickson's suggestion for forgetting.

Closely related to not doing and not knowing are the related hypnotic forms of Losing Abilities, The Negative, Doubt, Contradictions, and The Apposition of Opposites. We will now take up each of these in turn.

Losing Abilities

Erickson likes to phrase suggestions in the form of Losing Abilities because it is easy to experience, it is compatible with the basic nature of trance, and it is a rather impressive demonstration of trance as an altered state. Losing abilities tends to depotentiate one's usual everyday reality orientation and thus make one more receptive to altered modes of experiencing.

It will be interesting to experience that moment when you can no longer hold your eyelids open.

You can lose the ability to lift your right hand from your thigh. And will it be surprising when you find you cannot stand up?

The Negative

Erickson has studied the use of the negative in great detail. He admired an actor who could say "no" in 16 different ways to express 16 different shades of meaning from "absolute no" to agreeable acquiescence. A few examples are as follows.

Won't you?

When expressed with a doubting tone of voice, this has a negative meaning—"You won't." It is used only when you don't want a subject to do something.

You will, will you not?

This is a use of a negative word: "not?" is turned into a positive by being enunciated with a questioning inflection. Erickson feels this phrase meets a subject's need for a negative to balance the positive "you will" that comes just before it; this sentence is thus example of his apposition of opposites.

Research has indicated that it is much more difficult to comprehend negative formulations (Donaldson, 1959). The use of the negative, therefore, tends to depotentiate consciousness. In trance, when one would rather "not do" it is easier just to go along with a suggestion than try to figure out all its implications.

Erickson also believes that the use of the negative is another way of maintaining psychological balance and compensation as we will discuss later in the *apposition of opposites.* The use of the negative also enables the therapist to proffer a negative onto which a patient's resistance may be discharged and displaced. The use of negatives may thus be regarded as another approach to dealing with the "resistant" patient. The use of negation with such patients actually utilizes their own negativity in a manner that can discharge its destructive aspects and redirect it into constructive channels.

The Negative for Reverse Suggestion

Another basic use of the negative is for indirect or reverse suggestion. On one occasion a patient insisted that he would not awaken. Erickson accepted that, while admitting it would be inconvenient since he had other patients to see that day. Then with utter sincerity Erickson mentioned that he hoped the patient would not have to go to the bathroom, since that would awaken him. Of course, the patient soon found that he did have an inexplicable need to use the bathroom and thus had to awaken. Another reverse suggestion might have been, "Fine, you can try to stay in trance and do not awaken." The word "try," said with a subtly doubting tone together with the implied effort it will require not to awaken, has the net effect of actually awakening the subject.

In the reverse situation, when we want to enhance the possibility of trance, we might say, "Try to stay awake, just try and do not go into trance." The subject usually resists trance heroically for a few minutes till he is exhausted from the implied effort and falls by default into trance. These effects of negative suggestion were early described by Baudouin (1920) as the law of reverse effort: the more one tries to resist a suggestion, the stronger he feels compelled to carry it out. Weitzenhoffer (1957) has described this law of reverse effort" as a pseudo-law. There is actually no clinical or experimental data that indicates there is an intrinsic and necessary relation between "trying to resist" and a "compulsion to carry it out." Weitzenhoffer (1975) believes the effectiveness of such formulations is due to their containing an implied suggestion to do the exact opposite of what is purportedly suggested.

Doubt

The use of doubt is a subtle process that Erickson frequently conveys with a doubting tone of voice on key words (placed in italics in the examples below). Erickson usually capitalizes on the minimal and perhaps unrecognized doubt already experienced by a patient. His statement about this doubt is thus as much a truism as a suggestion. Whatever the doubt, it does place the person in a less stable position and thus propels one into a search for more structure and certainty. Erickson, of course, then provides therapeutic suggestions that will help restructure the patient in a satisfactory manner.

Do you really understand? means, "distrust your conscious understanding".

And you will really understand means the same as, "You don't really understand".

Do you think you are wide awake? implies, "You are not awake."

You are quite certain of yourself now, are you? implies, "You are not."

Contradictions

Revealing contradictions within patients' minds demonstrates the inadequacy of their usual beliefs and prepares the way for a positive attitude toward an experience with therapeutic trance. Erickson makes something of a game of this as he helps a patient to realize contradictions between thought and feeling and, of course, between the conscious and unconscious. He frequently uses ideomotor movements as a proof of these contradictions. Thus, when a patient protests that an important memory is not available, Erickson may establish a convincing contradiction, as follows:

If your unconscious thinks you have a better memory [feeling, thoughts, or whatever the patient has doubts about], your hand will lift.

When the hand does lift autonomously, it tends to convince the patient that with further hypnotic work the memory may soon become available.

When a patient doubts whether trance has been experienced, Erickson will use ideomotor movements to establish it.

Your conscious mind may doubt, but if your unconscious knows you have experienced trance, it will let your head nod slowly in the affirmative.

Erickson can thus frequently utilize the obsessive, ambivalent, and doubting aspects of a patient's ideation in a creative manner. The obsessive-compulsive personality can be understood as one laden with contradictions between the conscious and unconscious. These contradictions can be explored to establish rapport and cooperation between the various tendencies within the personality.

Apposition of Opposites

Another of Erickson's indirect forms of hypnotic suggestion is his penchant for the close juxtaposition, or apposition, of opposites. This seems to be a basic element in his confusion techniques, but it also may be a means of utilizing another natural mental mechanism to facilitate hypnotic responsiveness.

In the second Session Erickson illustrated the careful balancing, or apposition, of the opposite processes of remembering and forgetting. Kinsbourne (1974) has discussed how the "balance between opponent systems" is a basic neurological mechanism that is built in the very structure of the nervous system. What we are labeling as the "apposition of opposites" may be a means of utilizing this fundamental neurological process to facilitate hypnotic responsiveness. In this case Erickson was apparently balancing the opponent

systems of remembering and forgetting without the patient making a conscious effort to do either. Another apparent balancing of these opposites that is actually a double bind is as follows:

You can forget to remember or remember to forget.

Other modalities for the apposition of opposites are in lightness and heaviness, warmth and coolness, relaxation and tension, etc.

As your hand lifts, your eyelids will feel heavy.

This juxtaposition of lifting and lightness with heavyness utilizes the balance between opponent systems in another way. If we emphasize lightness and levitation, then we are shifting the subject out of equilibrium so there will develop within the subject a countertendency to balance and oppose the lightness with heaviness. This natural countertendency could eventually defeat the levitation suggestions. If we utilize this natural countertendency to heavyness by suggesting another response where it can be useful (eyelids heavy), however, we are actually utilizing the balance between opponent processes in a way that will facilitate two hypnotic suggestions. It is a way of offering multiple tasks that can reinforce each other. Other examples of the planned use of such apposition is as follows.

You can remain comfortable immobile until the urge to move takes your hand across the page writing automatically.

You may either see an unexpected image in the crystal ball or not see the ball at all.

As your hand becomes warmer, your forehead can become cooler. As you make that tight fist, the lower part of your body can relax.

Exercises with the Apposition of Opposites

1. Formulate suggestions utilizing the apposition of opposites warmth and coolness, tension and relaxation, anesthesia and hypersensitivity to touch. An interesting use of the latter for a refractory case of dental anesthesia is described by Erickson (1958). After a number of unsuccessful efforts by others Erickson was able to facilitate an effective oral anesthesia for dental work by first suggesting that the patient's left hand would become hypersensitive to all stimuli and needed to be carefully protected at all times. This was in keeping with the patient's fixed belief that dental work was always associated with hypersensitivity. Erickson simply displaced that hypersensitivity from the mouth to the hand. Erickson comments, "When this rigid understanding was met, dental anesthesia could be achieved, in a fashion analogous to the relaxation of one muscle permitting the contraction of another."

2. Conceptualize other opponent processes in the sensory, perceptual, and cognitive realms that can be used to facilitate hypnotic responsiveness.

3. Formulate apposition of opposites that could be utilized to facilitate all the classical hypnotic phenomena.

SIX

Facilitating Hypnotic Learning

The relations between the conscious and unconscious and Erickson's means of dealing with them are explored in this session. It is apparent that Erickson, like most pioneers in depth psychology, really believes in the value of the unconscious as a useful concept in his daily work with people. He carefully points out how the conscious and unconscious each have their own interests and how successful hypnotic work frequently depends upon appealing to both. As usual, he has an indirect approach for dealing with this problem. Erickson believes that analogies are a means of simultaneously appealing to the conscious and unconscious. As such, analogies are a basic tool for facilitating hypnotic learning.

Because of this, Erickson employs a rich repertory of analogies drawn from everyday life. It will be seen that many of these analogies are about the perceptions and experiences of childhood; the child's ways of functioning are closer to unconscious, which Erickson is trying to facilitate in trance work. He likes to use examples from his own experience because he knows them best, and his sense of conviction helps mobilize similar experiences within the patient. His analogies always fixate (or bore) the attention of consciousness while simultaneously instructing the unconscious. The conscious mind does not know how to do certain things. That is why the person is in therapy. The individual's unconscious does have the resources for doing what is necessary. Analogies are frequently an effective approach for mobilizing these unconscious resources.

Expectancy and Giving up Preconceptions

E: Do you have any questions?

S: I had a couple of questions, but I can ask them later. E: Ask them now.

S: I still wasn't clear yesterday why you didn't follow through when you put me in a trance. It wasn't clear.

You said you wanted me to experience it or something?

I understand that a hypnotherapist should experience a trance, but I wasn't quite clear in my mind what you were doing,

but maybe it isn't important for me to know.

> E: You never completely satisfy your audience. You leave them wishing for more. That's what is happening here. She is asking, "Why didn't you do more with me?" That impresses upon them that they really do want more.
>
> R: You have induced a situation wherein she is asking you for more and may thus break through some of her limitating preconceptions. The fact that she finally admits that "maybe it isn't important for me to know" suggests she may be giving up some of her reliance on consciousness.

Separating the Conscious and Unconscious: Relying on the Unconscious

E: I wanted your unconscious mind to have the liberty of doing something while your conscious mind was filled with other things.

and you wouldn't know your unconscious was active because you are being so interested in conscious activity.

S: Yes, what was going on here.

I was curious about what I did with L.

Couldn't that be considered a kind of hypnosis having her relaxed and concentrated on being in a different place?

E: Yes.

S: I think that can only be done by a good subject.

E: A good subject or a sophisticated one? What other questions have you?

S: That's all.

> E: I'm making it apparent here that there are two sets of interests, and the unconscious is going to have its interests.
>
> R: You're carefully pointing out the separation of conscious and unconscious interests.

E: You can't make that too obvious or too plain. You have to rely on the unconscious.

Hand Contact in Trance

[S gets ready to enter trance, but her hands are neatly folded together in her lap.]

E: One of the things that I found very important is, don't let the hands remain in contact with each other. Just how the contact of the hands interferes, I don't know.

(Pause.)

Now go all the way.

(Pause.)

> E: In folk language, "You have to hang together." When your hands touch each other, they tend to hang together. But you want an openness to stimuli—not something that is hanging together and excluding.

Unconscious Learning

Your unconscious learned a lot yesterday.

(Pause.)

It also learned

that

we could learn a lot

without

intruding upon the personality.

(Pause.)

All subjects,

whatever their degree of sophistication,

are uncertain that they can do

everything,

and yet

in their personal history

they can.

(Pause)

I have hunted for a book in a bookcase

under the impression,

within the frame of reference,

that it was bound in red.

I was unable to find it.

I could resort to reading all the titles of every book

and still not be able to find it

even though I read all the titles.

The title had no meaning

because my reference was red

instead of blue, which was the correct color.

E: "Your unconscious learned a lot yesterday."

(Erickson and R here discuss the case of Mrs. K, whose active and conscious mind derogatorized her unconscious' very acute "literalism" while in the trance state. So acute was her literalism that it even surprised Dr. Erickson. That literalism was an "accomplishment" of the unconscious, but Mrs. K's conscious mind regarded it as error.)

E: The conscious mind downgrades unconscious accomplishments, and you can't allow that downgrading to continue because conscious emotions filter down to the unconscious.

R: You mean the negative sets of consciousness can inhibit unconscious potentials?

E: The unconscious is going to be protective of consciousness. R: You mean it will go along with the conscious bias?

E: It's going to try to reassure the conscious mind with, "You don't have to be depressed if you didn't do things." The unconscious won't say, "You did something even though you didn't know it (e.g., Mrs. K's acute literalism). It doesn't function that way. It just says, "You don't have to worry because you failed."

R: That is how the unconscious protects the conscious mind?

E: The unconscious mind, with all due respect, does not tell the conscious mind, "You're wrong?"

R: It says instead?

E: "You don't have to feel bad about it." So you must see to it that the conscious mind gets the impression, "I only think I've failed."

R: That's how you correct the conscious mind.

E: Yes. With Mrs. K. we had to assure her that I, Dr. Erickson, failed in my instructions to her and that her acutely literal response was a success as a hypnotic response on the part of the unconscious.

Objectivity:
Breaking Conscious Frames of Reference

That has happened to me many times.

It seems true to others.

Others who haven't been in a trance.

(Pause)

Now why wouldn't I have seen a book covered with blue when I read its title?

(Pause.)

Because we all have the ability not to see when we are wide awake,

and in trance state

that ability can be called upon at any time.

(Pause.)

E: This illustrates the biasing influence of a conscious set on true knowledge.

R: You're trying to tell S with all these examples, "Give up conscious biases and sets."

E: Don't let conscious frames of reference occlude your vision.

(Erickson here gives many everyday examples of how conscious sets, e.g., rose-colored glasses, continually interfere with an objective perception of things. What is an objective perception? Seeing from many points of view to get a rounded picture.)

Negative Hallucination Training

There are many times in the past when you haven't seen something that was there;

you haven't felt things that could be felt.

R: Now you're shifting into suggestions that may lead to an experience of negative visual hallucinations: not seeing, hearing, or feeling.

Utilizing Everyday Experiences to Evoke Hypnotic Phenomenon

It is a very common experience

to develop a hypnologic state

and arouse in the morning from your sleep and not know where you are.

Everybody has the experiences of deja vu.

(Pause.)

Those who have seen something before think they have as if it really happened to them.

Hearing something before that you really haven't,

of being someplace where you haven't been

but still think you have been there.

Everybody has those experiences.

Transforming a familiar experience

into an alien one,

not recognizing

that which is familiar,

not recognizing a place,

a sound,

feelings.

In hypnosis

you utilize

those past learnings.

R: You now review a number of fairly common everyday experiences to make certain hypnotic phenomenon seem plausible. The experience of deja vu is a nice analogy that may evoke associative pathways leading to positive hallucinatory experience. So you are carefully apposing the possibility of either a negative or positive hallucination in whatever sense modality it may occur. It is all very open-ended; you will accept and applaude whatever hypnotic experience she is ready to have.

E: Yes.

Psychological Objectivity from Multiple Points of View

One of the most charming experiences

that children can demonstrate—

and they all do—

they bend over and

look at the world from between their legs,

(Pause.)

because the world is so strange.

Some people remember doing that.

(Pause.)

Most do not remember.

(Pause.)

Memories are so many times

discovered to be false

when they are true memories.

It is due to a change in the person that's not been recognized.

E: This is a terribly important experience. In psychotherapy you have to look at a problem upside down and sidewise.

R: To break out of your conscious sets.

E: You have to look at your patient as if you were sitting on a seat higher than his. You also have to look at him from a much lower seat. You need to look at him from the other side of the room. Because you always get a totally different picture from different points of view. Only by such a total look at the patient can you gain some objectivity.

R: All these different views add up to a more total objectivity.

E: That's one of the drawbacks of conventional psychoanalysis: you get just one view, 18 inches behind and to the left of the patient. That is a very stereotyped thing.

Plasticity of Perception and Behavior:
Facilitating Change by Breaking Conscious Sets

As examples

I can cite personal incidences.

(Pause.)

When I went back to the farm after being in college,

I found that the stove was unusually small.

(Pause.)

I remembered how I had to stand on my toes

to reach up to the warming oven.

My son Allan returned from Washington, D.C.,

walked through all the rooms of the house,

and remarked,

"I know it is impossible that these rooms have all shrunk.

They are much smaller,

very much smaller."

(Pause.)

(Erickson cites another example wherein one of his daughters as a baby looking up from her crib learned to associate his head with the ceiling, and the confusion this association entailed on a later occasion when she saw him closer to his true proportions.)

E: In hypnotic experiences

you do not try to correct your memories.

You receive them

without automatic correction.

I have watched babies' perception develop.

They start out by seeing one person standing by the crib

until one day,

without verbalizing it,

they now realize there are two.

It takes some length of time to differentiate between mother and father.

It takes still more time to differentiate between big brother or mother and to recognize three.

E: Pointing out here the child's frame of reference.

R: All of this is to train S to give up her conscious sets, to break down her conscious frameworks in preparation for change.

E: I want to make her aware that she has many, many rigid sets. Everybody has.

R: So this is a general understanding you try to give every patient in the beginning. You try to soften up their rigidities by talking of the plasticity of perception and behavior, etc.

E: That's right. You try to make the person aware. There is nothing wrong with having rigid sets. But if you want to alter yourself in some way, you must be unashamedly aware that you do have sets and it's better to have a greater variety of sets.

R: So you will have a much wider range in your behavior.

(Erickson here gives several clinical examples of how he gently broke through the inhibiting conscious sets of patients so they gradually began fuller self-exploration of their body, etc. (Haley, 1973; Rossi, 1973b).

Not Doing to Facilitate Early Memory and Age Regression

You have those learnings

in adult life, you can correct them,

(Pause.)

but there is no real need to correct them.

They should be appreciated.

A child sees a walking

stick

(Pause.)

As an adult she still shows her wonderment at the walking stick that is actually a snake.

Psychotherapy using hypnosis,

taking note of past memories

in their purity

without any need to correct them.

As you should want to know what they are.

(Pause.)

We learn to recognize those individual memories

without correcting them.

You then have an opportunity to assess, evaluate

the components of a total understanding.

You meet a person,

and for no reason at all you dislike that person,

but you do have a reason.

You have a walking-stick reason,

you have a head-between-legs-looking-at-the-world reason,

because you have seen something new in that person

in terms

of memories, of learnings.

But as an adult you usually correct these memories,

and you simply say you don't like that person

for no reason at all.

(Pause.)

I'll cite personal incidences,

as I know them better than other instances.

When I walked into the house and my son Lance,

then a small boy

had a problem.

He knew he could not see through a brick wall.

He could see only through windows.

Yet Daddy walked into the house

and said, "You were told not to play with that doily on the table."

He had played with it,

and he happened to be over by a window.

and saw me approaching.

So he carefully replaced the doily except he didn't center it on the table.

That was what he didn't know.

He then attributed my knowledge

that he was playing with the doily

to my being able to see through a brick wall.

(Pause.)

So far as the patient

is concerned

you do not remind yourself of adult understandings.

Nor do you look at behavior with adult understandings.

(Pause.)

> R: Here you suggest an hypnotic phenomenon (early memory) by *not doing* (no need to correct early memories and childhood distortions) so that it appeals as being effortlessly easy to one in a placid state of trance. This is actually an indirect approach to age regression. You don't directly tell her to age regress. By simply mentioning the ways in which a child sees the world differently, you are hoping to actually evoke her early modes of perception and thereby facilitate the possibility of a genuine age regression.
>
> E: That's right.

Questions as Indirect Suggestions: Displacing Doubt and Discharging Resistance

How soon

do you think

you will be willing

to open your eyes

and not see your hands?

E: What does this question really do? Put it into separate sentences:
1. You will open your eyes.
2. You will see.
3. You will not see certain things. Those are actually commands.

R: But they are stated in a question as a *fait accompli.*

E: Yes. It's stated as a question, but the only real question it asks is, "At what time will it be done?" You are displacing all doubt onto the question of the time. That is the only thing that needs to be doubted. All the rest is actuality.

R: You've done that with a question I would call an implied directive.

E: Yes. The common mistake in psychotherapy is to give a patient directions without recognizing there have to be doubts.

R: In our society we invariably doubt and test any suggestion that is made to us. This may be the social basis of the so-called resistance. Perhaps that is why the Freudians talk so much about resistances. The typical therapist does not know how to present directives in a way that would discharge resistances automatically as you have here illustrated. You are always discharging resistances and doubts by the way you express things.

Validating Suggestions for Negative Hallucination

You have not seen your hands many times in the past

when they were in direct line of vision.

(Pause.)

An adult can learn to see things

in direct line of vision.

And you also learned

not to see your hands

when they were in a direct line of vision.

(Pause.)

E: Now I tied that question to an actual thing: "You have not seen your hands many times in the past."

R: You validate the suggestion by juxtaposing it with a common perceptual experience of the past.

E: How many times have we not seen "the impossible not to see?"

R: As I'm looking at this microphone I'm holding in front of you right now I realize that I was not seeing my hand that's holding it.

E: That's right! A magician makes his living out of that. He utilizes your ability not to see what he is doing.

Conscious and Unconscious, Communication by Logic and Experience

[Here Erickson gives another fairly complex example of how adult and child memories of the same phenomenon can be different because of their different points of view.

Because of this we find that there are frequently two sets of memories, which sometimes gives rise to confusion in patients.]

E: In psychotherapy you learn to recognize how things can be different things.

(Pause.)

I am going to suggest that you open your eyes and keep them open, and be aware

not to see.

(Pause.)

[S opens her eyes and reorients to her body.]

R: So it is a good approach to tie your suggestions to an undeniable experience they have had. That tends to validate your suggestions. What are you trying to convince with these validating analogies from everyday life? The conscious or the unconscious?

E: The unconscious knows all about these things!

R: You're telling the unconscious what mental mechanisms to use by analogy.

E: Yes.

R: At the same time the logic of the analogy impresses the conscious mind. Would you say that?

E: The logic appeals to the conscious mind, and the unconscious has the conviction of actual knowledge (experiential knowing).

R: So you're speaking to both the logic of the conscious mind and the experience of the unconscious.

E: The conscious mind understands the logic of it, and the unconscious understands the reality.

R: What do you mean by reality here?

E: You just demonstrated it by seeing the microphone but not your hand.

R: The unconscious knows reality from concrete experiences. E: Yes.

R: When S opened her eyes and came out of trance, she rubbed her hands together as one of her typical acts of reorientation to her body, but she did not comment on whether or not she was actually seeing them. By implication we can assume that she was not seeing her hands since she was so absorbed in recounting her early memories. You did not tell her to awaken, but in her case the association between opening eyes and ending trance was stronger than your implication that she could open her eyes and remain in trance and not see.

Subjective Experience of Trance: Genuine Age Regression, Hypermenesia, and Amnesia

S: I had an experience

where I was actually a year old and looking up from a crib. There was an experience from three years old when I was drinking from cups and getting splashed on my left hand.

I was thinking about the feeling that I had. It's like the song about Alice, "She was ten feet tall,"

and I had the fear of getting a glass of water and having to bend over her because I was so tall.

E: And even that

you could do without terrifying emotions.

S: Yes, it was like untrue,

like I had been eating some magic mushrooms.

I guess you look at things different. That flashed through my mind when I tried to walk on stilts as a child.

It took all afternoon, and they finally did work.

E: And you saw things

very high?

S: They were! Those stilts were over my head.

[This session terminates with a recounting of the many memories that returned to S during her trance experience.]

Dr. S later wrote the following about her inner experience at this point.

"As I later read my remarks, I was confused because I could recall only the first part where I described myself as *being* in a crib. I remember that experience as though I actually were small and looking up at a big world (genuine age regression). I have amnesia now for the three-year-old incident, and the last one is not as I recall it. My recollection here is that I was thirsty after the trance work and wanted to go into the next room for a drink of water. However, I could not seem to mobilize myself. I could not pick up the glass of water by my chair. I was somehow still Alice in Wonderland, ten feet tall, so I was afraid that I would have to bend to get through the doorway and that might make me dizzy.

"My explanation is that I must have gone into a trance again as I began to describe the trance events. I recall that I was wearing a dress with long butterfly sleeves. My wrists were bent over the end of the arm of the chair and covered by my sleeves. This is in contrast to my usual habit of keeping them in my lap. Apparently since I had the impression that I could not pick up a glass, I had (in a complex fashion) followed the suggestion (unrecalled by me) of not seeing my hands.

"There is an unconscious!"

R: This was a fantastically successful trance experience for S. She managed to give up some of the limiting sets of her conscious mind, so she had an apparently genuine experience of age regression wherein she experienced herself in a crib and actually saw the world the way a child would. She experienced hypermenesia (the extensive recall of early memories) and, paradoxically, she also experienced an amnesia (she forgot some trance events). She acknowledges how she managed not to see her hands to comply in her own individual fashion with your suggestion and how this immobilized her so she could not even pick up a glass of water. You attempted to evoke a negative visual hallucination for her hands "when they were in direct line of vision." But apparently her unconscious could only manage not seeing her hands by immobilizing them out of her view at this time. It's really charming to witness her individuality: to immobilize is easier for her at this point than not seeing. And, most significantly for future hypnotic work, she really acknowledges the reality of the unconscious!

DISPLACING AND DISCHARGING RESISTANCE

In practical clinical work we find that "resistance" frequently means that the patient is stuck with a few patterns of association and experience that are interfering with opportunities for new learning. We thus tend to view resistance as an erroneous mental set that gets in the way of new experience. Resistance need not always be understood in the psychoanalytic sense as something that is continually maintained by deep and unconscious forces. Rather, resistance can be a relatively simple wrongheaded attitude that prevents people from utilizing their own abilities.

Erickson has developed a number of approaches for displacing and discharging resistance that seem merely humorous, clever, and superficial. These approaches can help patients dodge free of their own "mental blocks" in relatively short order, however.
In a typical case an aggressive patient may enter the situation blustering, "I need hypnotherapy and I'm sure I can't be hypnotized." On one such occasion Erickson happened to have three other empty chairs in the office and proceeded as follows:

E: There is, of course, a possibility that you can be hypnotized. (Pause.)

Erickson opens the door by mentioning the "possibility" of trance.

There is more possibility that you can't be hypnotized.

He then reinforces or gains acceptance of that "positive possibility" by his open acknowledgment and acceptance of the patient's negative attitude. The patient immediately feels respected, and a positive rapport is established.

Now let's try this chair.

Implying that the question of going into trance has something to do with which chair is being used. This begins the process of displacing the resistance from the patient to the chair.

If you fail in this one, there is still the possibility that you can go into trance.

This gives the patient an opportunity to fail and thus prove his point that he "can't be hypnotized." This initial failure allows the patient to "use up" and discharge his resistance.

[The patient failed to enter trance in three of the chairs. He finally experiences a satisfactory trance in the fourth chair. Each time he failed he "used up" another increment of resistance until trance became inevitable because of the way the above implication displaced the resistance from the patient to the details of seating arrangements, etc.]

Erickson will typically vary the procedure slightly with each effort (e.g., shifting direction of the chairs, shifting his chair, altering the induction procedure to find the one most satisfactory to the patient.

Another means of displacing and discharging resistance is through games and seemingly irrelevant but humorous challenges whereby the therapist actively evokes and then discharges the resistance by way of a predictable denouement.

As an example, say that you have a bunch of marbles only one of which is a solid color. You tell a child that you are going to write down on paper which marble he is going to choose. You take the position that you are going to predict and force the child to accept your choice. The child accepts the challenge and maintains that you cannot predict his choice. You then begin describing the various marbles as his possibilities: the blue one with white stripes, the brown and white, and so on. He hears you describing all the marbles in a seemingly random manner. He does not notice that you always pick a color combination. He can escape by picking a marble with no color combination—the solid color marble that you previously wrote down as his eventual choice.

In this case you create the resistance by saying, "I can predict your choice." You insisted that he was going to choose one of the color combinations you mentioned, but he puts an end to your speculations by choosing the solid color you had previously predicted when you wrote it down. The child does not know how you did it, yet there was a genuine rationale for predicting his choice. The child is now intrigued and open to other things you have to say to him.

The same procedure can work with a resistant adult. You look at the bookcase in your office and say that you can predict which book the patient will choose. You then mention all the various possibilities of choice: the dark books with light printing and those that are the reverse, the multicolored bindings, the odd-sized books, and others. You carefully avoid mentioning just one book. Patients invariably resist all the possibilities you mention and pick the one you did not. Patients experience a *surprise* upon finding out that you had written down their choice before the game started. Their resistance tends to remain in the bookcase, and they are now simply open and curious about what you are up to. When the whole procedure is carried out in a low key, fun manner rapport is enhanced. Any serious challenge, of course, is to be avoided with an adult. Should the therapist fail to predict the book that the patient chooses, all is not lost. The patient is now "one up" and feels more relaxed; he now owes it to the therapist to be obliging by entering trance, etc. Resistance has been discharged in the play, and the patient is now available for therapeutic work.

Erickson's efforts to displace doubt and discharge resistance are a unique contribution to psychotherapy. It is clear that this approach can be useful in any form of therapy where careful consideration is taken to help the patient circumvent his own learned limitations in order to achieve something new.

Erickson provided another example of a very common situation in therapy where he regularly displaces doubt and discharges resistance as follows:

E: A woman patient came to me with a great many doubts about how much she could tell me. So I said, "All right, hold back everything that you could possibly have some doubt about telling me."

R: So that immediately mobilized in her mind all the possible things she could say.

E: Yes, by the end of the hour she told me everything because once she told me one thing it led to the next. She finally found she had nothing she had any doubts about telling me. An analyst could have dealt with those resistances for several years.

R: Whenever you give important directives, you try to provide a lightning rod to discharge their resistances.

E: Without bringing an awareness of that resistance into the foreground. You don't want your patient to think about resistances.

R: You discharge resistances without their even being aware that it is happening.

E: To discredit this as manipulation is as faulty as it is to describe food as being manipulated because you have seasoned it properly.

Further insight into Erickson's approach to discharging negativity and resistance is in the way he gets a patient's "no" away from the therapy situation and gradually replaces it with "yes." With a resistant patient ("resistant" here means there is a lack of understanding; one usually resists when, because of a lack of understanding, one anticipates harm) he sometimes begins by saying, "You don't like all that smog out there do you?" Of course the patient answers with "no." Erickson then continues with a series of questions that elicit a "no" response about things far removed from the therapy situation. This process gives patients an opportunity to displace and discharge their resistance away from the therapy situation. Erickson then proceeds to ask questions that will elicit a "yes" about the therapy situation (e.g., Are you as comfortable in that chair as you can be?")

The "yes" responses then generalize to a greater extent than the patient realizes. One question about comfort, for example, does not convince patients that the therapist is

concerned about their comfort and welfare. But a series of questions about comfort begins to generalize through the patient's associative process. The possibility of comfort, for example, now becomes associated with the difficult or traumatic material the patient is struggling to express.

It is apparent that Erickson is using a *process orientation* to shift *resistance and "no"* out of the therapy situation and to bring *comfort and "yes"* into the therapy situation. That is, the actual *content* of the "no" or "yes" is irrelevant. Any expressed "no" will help discharge negativity regardless of its particular content. Any expressed "yes" will generalize further cooperation regardless of the subject matter.

On careful reflection it will be found that this orientation to *process* is more frequently prominent in Erickson's approach than his concern about *content.* In inducing trance, for example, he utilizes the *process* of confusion to depotentiate consciousness; the actual subject matter or content of the confusion is irrelevant. In training a hypnotic subject it is the process of experiencing one and then a series of hypnotic phenomena that is important, not the content of the particular phenomena. In facilitating therapy it is the process of getting any noticeable improvement that is important, even if it is initially far removed from the content of the patient's most pressing problem. Content, to be sure, is important, but its importance is usually as a vehicle to gain entry to the patient's attention and associative structures where the process of therapy can be facilitated.

Exercises in Displacing Doubt and Resistance

1. *Discharging resistance in everyday life.* Think of occasions in which you were firmly against something and to your surprise found yourself going along with it nonetheless. You may later criticize yourself for "compromising," "giving in," or having "weak willpower." But actually you were probably caught in a situation where your resistance was intentionally or accidentally discharged by another person or circumstances. Can you recall your feelings at the moment when you "gave in?" Can you trace out the psychodynamics of how your resistance was discharged? Can you formulate how you could utilize this example of discharging resistance in a psychotherapeutic situation?

2. Keep a record of all your examples of displacing doubt and discharging resistance in everyday life and psychotherapy. When you have enough examples, try to formulate some general hypotheses about the psychodynamics of displacing doubt and discharging resistance. Can you now design psychological experiments that could test the validity of your hypotheses? Publish your results!

MULTIPLE LEVELS OF COMMUNICATION: ANALOGY, PUNS, METAPHOR, JOKES, AND FOLK LANGUAGE

Erickson's penchant for communication by analogy is herein explained as communication on two levels: the conscious and the unconscious. The logic of an analogy can appeal to the conscious mind and break through some of its limiting sets. When the analogy also refers to deeply engrained (automatic and therefore functionally unconscious) associations, mental mechanisms, and learned patterns of behavior, it tends to activate these internal responses and make them available for problem solving. Suggestions made by analogy are thus a powerful and indirect twofold approach that mediates between the conscious and unconscious. Appropriate analogies appeal to the conscious mind because of their inherent interest while mobilizing the resources of the unconscious by many processes of association.

The authors (Erickson and Rossi, 1976) have discussed multilevel communication in terms of Jenkins' contextual theory of verbal associations (1974). Analogy, puns, metaphor, paradox, and folk language can all be understood as presenting a general context on the

surface level that is first assimilated by consciousness. The individual words and phrases used to articulate that general context, however, all have their own individual and literal associations that do not belong to the context. These individual and literal associations are, of course, usually suppressed and excluded from consciousness in its effort to grasp the general context. These suppressed associations do remain in the unconscious, however, and under the special circumstances of trance, where dissociation and literalness are heightened, they can play a significant role in facilitating responsive behavior that is surprising to consciousness.

This situation can be made clear by analogy. The adult reader is usually searching for an author's meaning. Within certain limits it really doesn't matter what particular sentences or words are used. Many different sentences and combinations of words could be used to express the same meaning. It is the meaning or the general context of the sentences that registered in consciousness, while the particular sentences and words used fall into the unconscious and are "forgotten." In the same way one "reads" the meaning of a whole word rather than the individual letters used to make up the word. The general context of the letters registers as the conscious meaning of a word rather than the individual associations of each letter. Jenkins (1974) has summarized the data of recent experimental work in the area of verbal association, event recognition, information integration, and memory that places a similar emphasis on the significance of context to understand these phenomena. In any discourse or phenomena using words it is usually the general context that establishes meaning rather than the structural units that create the discourse.

The obvious exceptions to this, of course, are in puns, allusions, and all sorts of verbal jokes where the punch line depends on literal or individual verbal associations to words and phrases that originally escaped the attention of consciousness. Verbal jokes depend on literal or individual associations that are usually suppressed.

In the same way Erickson's two-level communication utilizes a general context to fixate the attention of consciousness while the individual associations of words, phrases, or sentences within that context are registered in the unconscious, where they can work their effects. From this point of view Erickson's Interspersal Technique (1966) is the clearest example of two-level communication wherein subject matter of interest to a particular patient is utilized as a general context to fixate conscious attention while interspersed suggestions are received for their effects on an unconscious level.

Erickson has devised a number of other techniques to activate the individual, literal, and unconscious associations to words, phrases, or sentences buried within a more general context. Turns of phrase that are shocking, surprising, mystifying, non sequiturs, too difficult or incomprehensible for the general conscious context, for example, all tend momentarily to depotentiate the patient's conscious sets and to activate a search on the unconscious level that will turn up the literal and individual associations that were previously suppressed. When Erickson overloads the general context with many words, phrases, or sentences that have common individual associations, those associations (the interspersed suggestion) gain ascendancy in the unconscious until they finally spill over into responsive behavior that the conscious mind now registers with a sense of surprise. The conscious mind is surprised because it is presented with a response within itself that it cannot account for. The response is then described as having occurred "all by itself without the intervention of the subject's conscious intention; the response appears to be autonomous or "hypnotic."

Analogy and metaphor as well as jokes can be understood as exerting their powerful effects through the same mechanism of activating unconscious association patterns and response tendencies that suddenly sum-mate to present consciousness with an apparently "new" datum or behavioral response.

THE MICRODYNAMICS OF SUGGESTION

Once Erickson has fixated and focused a patient's attention with a question or general context of interest (e.g., ideally, the possibility of dealing with the patient's problem), he then

introduces a number of approaches designed to depotentiate conscious sets. By this we do not mean there is a loss of awareness in the sense of going to sleep; we are not confusing trance with the condition of sleep. In trance there is a reduction of the patient's foci of attention to a few inner realities; consciousness has been fixated and focused to a relatively narrow frame of attention rather than being diffused over a broad area, as in the more typical general reality orientation (Shor, 1959) of our usual everyday awareness. When fixated and focused in such a narrow frame, consciousness is in a state of unstable equilibrium; it can be "depotentiated" by being shifted, transformed, or bypassed with relative ease.

Erickson believes that the purpose of clinical induction is to focus attention inward and to alter some of the individual's habitual patterns of functioning. Because of the limitations of patients' habitual frames of reference, their usual everyday consciousness cannot cope with certain inner and/or outer realities, and they recognize that they have a "problem." Depotentiating patients' usual everyday consciousness is thus a way of depotentiating facets of their personal limitations; it is a way of deautomatizing (Deikman, 1972) an individual's habitual modes of functioning so that dissociation and many of its attendant classical hypnotic phenomena (e.g., age regression, amnesia, sensory-perceptual distortions, catalepsies, etc.) are frequently manifest in an entirely spontaneous manner (Erickson and Rossi, 1975). Depotentiating the limitations of the individual's usual patterns of awareness thus opens up the possibility that new combinations of associations and mental skills may be evolved for creative problem solving within that individual.

Erickson's approaches to depotentiating conscious sets are so subtle and pervasive in the manner with which they are interwoven with the actual process of induction and suggestion that they are usually unrecognized even when one studies a written transcript of his words. In order to place them in perspective we have outlined the microdynamics of induction and suggestion in Table 1 as: (1) the Fixation of Attention; (2) Depotentiating Conscious Sets; (3) Unconscious search; (4) Unconscious Processes; and (5) Hypnotic Response. We have also listed a number of Erickson's approaches to facilitating each stage. Most of these approaches are illustrated in this volume and are discussed in more detail elsewhere (Erickson and Rossi, 1974; Erickson and Rossi, 1975; Haley, 1967; Rossi, 1973). Although we may outline these processes as stages of a sequence in Table 1 for the purpose of analysis, they usually function as one simultaneous process. Because of this, and in order to distinguish these processes from the broader dynamics of induction and mediating variables previously outlined (Barber and DeMoor, 1972) we designate ours as "microdynamics." When we succeed in fixating attention, we automatically narrow the focus of attention to the point where one's usual frames of reference are vulnerable to being depotentiated. At such moments there is an automatic search on the unconscious level for new associations that can restructure a more stable frame of reference through the summation of unconscious processes. There is thus a certain arbitrariness to the order and the headings under which we assign some of the approaches Erickson used in Table 1. He could equally well begin with an interesting story or pun as with a shock, surprise, or a formal induction of trance. Once the conditions in the first three columns have been set in motion by the therapist, however, the patient's own individual unconscious dynamics automatically carries out the processes of the last two columns.

Table 1
The Microdynamics of Trance Induction and Suggestion

(1) *Fixation of attention*	*(2)* *Depotentiating Conscious Sets*	(3) Unconscious Search	(4) *Unconscious Process*	(5) Hypnotic Response
1. Stories that motivate, interest, fascination, etc. 2. Standard eye fixation 3. Pantomime approaches 4. Imagination and visualization approaches 5. Hand levitation 6. Relaxation and all forms of inner sensory, perceptual or emotional experience etc.	1. Shock, surprise, the unrealistic and unusual 2. Shifting frames of reference; displacing doubt, resistance and failure 3. Distraction 4. Dissociation and disequilibrium 5. Cognitive overloading 6. Confusion, non sequiturs 7. Paradox 8. Binds and double binds	1. Allusions, puns, jokes 2. Metaphor, analogy, folk language 3. Implication 4. Implied directive 5. Ideomotor signaling 6. Words initiating exploratory sets 7. Questions and tasks requiring unconscious search 8. Pause with therapist attitude of expectancy	1. Summation of: a) Interspersed suggestions b) Literal associations c) Individual associations d) Multiple meaning of words 2. Autonomous, sensory and perceptual processes 3. Freudian primary processes 4. Personality mechanisms of defense	"New datum of behavioral response experienced as hypnotic or happening all by itself"

	9. Conditioning via voice dynamics, etc. 10.Structured amnesia 11.Not doing, not knowing 12.Losing abilities, the negative, doubt etc.	9. Open-ended suggestions 10.Covering all possibilities of response 11.Compound statements 12.Intercontextual cues and suggestions etc.	5. Ziegarnik effect etc.	

A number of Erickson's most interesting approaches to facilitate hypnotic response are the hypnotic forms listed in column 3 of table 1. All these approaches are designed to evoke a search on the unconscious level. Allusions, puns, metaphors, implications, and so on are usually not grasped immediately by consciousness. There is a momentary delay before one "gets" a joke, and in part, that is what is funny about it. In that delay period there obviously is a search and processes on an unconscious level (column 4) that finally summate to present a new datum to consciousness so that it gets the joke. All the approaches listed in column 3 are communication devices that initiate a search for new combinations of associations and mental processes that can present consciousness with useful results in everyday life as well as in hypnosis. The hypnotic forms listed in columns 2 and 3 are also the essence of Erickson's indirect approach to suggestion. The study of these approaches may be regarded as a contribution to the science of pragmatics: the relation between signs and the users of signs (Watzlawick, Beavin, and Jackson, 1967). Erickson relies upon the skillful utilization of such forms of communication, rather than hypersuggestibility per se, to evoke hypnotic behavior.

As noted in Chapter One, it is important to recognize that while Erickson thinks of therapeutic trance as a special state (of reduced foci of attention), he does not believe hypersuggestibility is a necessary characteristic of such trance (Erickson, 1932). That is, just because patients are experiencing trance, it does not mean they are going to accept and act upon the therapist's direct suggestions. This is a major misconception that accounts for many of the failures of hypnotherapy; it has frustrated and discouraged many clinical workers in the past and may have impeded the scientific exploration of hypnosis in the laboratory. Therapeutic trance is a special state that intensifies the patient-therapist relationship and focuses the patient's attention on a few inner realities; *trance does not ensure the acceptance of suggestions*. Erickson depends upon certain communication devices such as those listed in column 3 to evoke, mobilize, and move a patient's associative processes and mental skills in certain directions to *sometimes* achieve certain therapeutic goals. He believes that hypnotic suggestion is actually this process of evoking and *utilizing* a patient's own mental processes in ways that are outside his usual range of ego control. This *utilization theory of hypnotic suggestion* can be validated if it is found that other therapists and researchers can also effect more reliable results by carefully utilizing whatever associations and mental skills a particular patient already has that can be mobilized, extended, displaced, or transformed to achieve specific "hypnotic" phenomena and therapeutic goals.

In the therapeutic trance situation the successful utilization of unconscious processes leads to an autonomous response; patients are surprised to find themselves confronted with a new datum or behavior (column 5). The same situation is in evidence in everyday life, however, whenever attention is fixated with a question or an experience of the amazing, the unusual, or anything that holds a person's interest. At such moments people experience the common everyday trance; they tend to gaze off (to the right or left, depending upon which cerebral hemisphere is most dominant, (Baken, 1969; Hilgard and Hilgard, 1975) and get that "faraway" or "blank" look; their eyes may actually close, their body tends to become immobile (a form of catalepsy), certain reflexes (e.g., swallowing, respiration) may be suppressed, and they seem momentarily oblivious to their surroundings until they have completed their inner search on the unconscious level for the new idea, response, or frames of reference that will restabilize their general reality orientation. We hypothesize that in everyday life consciousness is in a continual state of flux between the general reality orientation and the momentary microdynamics of trance as outlined in Table 1. The well-trained hypnotherapist is acutely aware of these dynamics and their behavioral manifestations. Trance experience and hypnotherapy are simply the extension and utilization of these normal psychodynamic processes. Altered states of consciousness—wherein attention is fixated and the resulting narrow frame of reference is shattered, shifted, and/or transformed with the help of drugs, sensory deprivation, meditation, biofeed-back, or whatever—follow essentially the same pattern but with varying emphasis on the different stages. We may thus understand Table 1 as a general paradigm for understanding the genesis and microdynamics of altered states and their effects upon behavior.

Exercises with Analogies Puns, and Metaphors

1. Create analogies and metaphors that are interesting and arresting to the conscious mind while also activating habitual modes of unconscious functioning that can be used to facilitate all the standard hypnotic phenomena.

2. When planning a therapeutic approach to a particular patient's problem, utilize puns, analogies, metaphors, and folk language that will have the following:

a. A direct appeal for that individual in terms of his lifetime interests.

b. Directly activate by association habitual modes of functioning in the patient that can facilitate a therapeutic goal.

Note that such analogies can be effective with or without trance. In trance, however, analogies can be considered as specific tools for facilitating desired responses.

SEVEN

Indirectly Conditioned Eye Closure Induction

Erickson continues in this session to deal with Dr. S's major problem in learning to experience trance: allowing and trusting unconscious modes of functioning. This is the most typical problem the modern hypnotherapist must learn to cope with in our western culture where the rational aspect of mind is valued above all others. It is the bias and hubris of the rational and intellectualized mind to downgrade the accomplishments and possibilities of the unconscious. The conscious mind likes to believe in its autonomy and power. In actuality, consciousness is always focal and thus limited to what is within its momentary focus. It cannot possibly deal with everything all at once; at every moment in our lives we are dependent on unconscious processes (to regulate everything from our blood chemistry to our next verbal association). Consciousness is a relatively recent evolutionary acquisition. Although we like to believe that consciousness is a high form of evolutionary development, it is in fact extremely labile and limited in its abilities.

A major problem of consciousness as it is presently constructed is that it frequently excludes everything outside of its immediate focus and it tends to believe only in its own momentary mood and truth. No wonder there are so many lethal conflicts within us as individuals and between us as people. Because of these limitations it is important that consciousness be expanded (awareness heightened) by learning to relate optimally to the unconscious. For Erickson this would mean allowing the unconscious an opportunity to do its own work. Therapeutic trance can be understood as a state in which unconscious work is to some extent freed from the limiting foci and sets of consciousness. Once the unconscious has done its work, the conscious mind can receive and focus it appropriately in the various moments and sets (circumstances) of life. The unconscious is a manufacturer and consciousness is a consumer; trance is a mediator between them.

Erickson begins the session with remarks that tend to confuse and depotentiate consciousness. He then demonstrates another indirect approach to induction by conditioning eye closure. He emphasizes the need for careful observation of trance induction by a scaling procedure. Of particular value in the commentaries of this session are examples of Erickson's unusual perceptiveness in dealing with a number of difficult issues in trance work, including sources of psychological confusion, "lies" in trance, alternating rhythms of suggestibility in trance, posthypnotic suggestion, dealing with spontaneous awakening, and ways of protecting the subject in trance.

Confusion in Trance Induction

Erickson begins the session by asking S what she would like to accomplish today. S mentions a wart she would like to have go away but does not volunteer any personal problems she might want to deal with. A desultory conversation takes place for a few minutes. Then Erickson quietly remarks, "Probably Dr. Rossi is noticing something." This was a hint to R to notice that S's eye blink reflex was spontaneously beginning to slow down. R isn't sure just what is happening, but he is aware Erickson is telling him to observe S carefully. S laughs self-consciously and asks what is going on. Erickson assures her that she will know soon enough. After a moment's pause Erickson continues.

E: How soon do you think you will know?

S: I don't even know what I'm supposed to know. What I'm ready for?

(Pause)

What am I supposed to know?

(Pause.)

R: You frequently use this approach of hinting that something is happening that the patient's consciousness is not tuned into. It tends to confuse the patient, it depotentiates the ego's subjective sense of control, and it builds up a high expectancy that something unusual and significant will happen. Her questions clearly indicate the great confusion that has been induced by your simple remark, "Probably Dr. Rossi is noticing something."

Indirectly Conditioned Eye Closure Induction

E: Now I'll say odd and even for a specific purpose.

S: Will you tell me?

E: At the end.

Even.

Odd.

(Pause.)

Odd.

Odd.

Odd

Even.

(Pause.)

[S is obviously puzzled by Erickson's odd-even statements. He is talking in a way that is apparently meaningful, yet she cannot grasp his meaning. After a moment of concentrated attention she apparently gives up and lapses into herself]

E: You say "odd" when the eye blink is slow and "even" when it is fast.

R: You just say that without her being aware of what you were doing?

E: Yes.

R: What does that do to her?

E: She makes the connection unconsciously. She begins with two blinks, one fast and one slow. Unconsciously she noticed that I said "odd" after the slow blink. So then she pauses and then blinks slow three times. She gives a more rapid blink and pauses again.

R: This is an induction procedure or what?

E: It is an induction procedure because you're closing the eyelids. It is a technique to close the eyelids.

R: Why will the eyelids close? E: Because it becomes a conditioned response. "Odd" becomes associated with a sensation of slowness if you say it each time there is a slow blink.

R: Once you've established that association, you need only say "odd" and the eyelids will get slower and slower and finally close. Is this another subtle or indirect way of inducing trance? Is it an unconsciously conditioned response for induction?

E: Yes. It's an unconsciously conditioned response.

Observation Scale for Hypnotic Depth

She is going back and forth on a scale of 1 to 100.

S: I usually don't blink so much.

E: Now she is up to about 15.

(Pause.)

50

35, 40

15, close

[To R: Now I let that be prolonged. I interrupted it so it could be demonstrated thoroughly. Ordinarily you wouldn't make prolonged use of this. This is a chance for you to see it in operation.]

E: On a scale of 1 to 100 where a 100 is deep trance. When the eyes close when you say "close," the subject is perhaps at 10.

R: You are using your own subjective scale when you say she is up to 15, 50, etc. When she was up to 15, I noticed her face beginning to iron out. At 40 I noticed more quietness.

E: I said "close" here when the eyes were closing on a slow blink, and that served to close them.

Trance as Experiential Rather Than Intellectual Learning

Now I know that S wants to drift.

(Pause.)

Now there you saw the conscious mind recognizing a word of significance. After a while she will let the drifting remain unconscious.

(Pause.)

[To S] Now searching through things you really want

for many different reasons,

not only for an understanding of them

but for an experience of them.

(Pause.)

R: At the word "drift" there was a visible relaxing of S that was apparently mediated by ego consciousness, since it was obvious and quick. When relaxation is mediated by the unconscious, it is somehow more subtle. Her conscious mind recognized the work "drift" as her own description of deepening trance (see end of first session).

E: Now S has been trying to get some rational understanding of hypnosis. She doesn't realize that to learn to swim you have to get in the water to actually experience it. Intellectual book knowledge about swimming won't do it. She has been trying to get in the trance and understand. But she should just get in the water first.

R: When the patient tries to observe and understand, it interferes with the process of learning by the experience of just letting things happen. In trance it is necessary to learn by experiencing rather than intellectualizing.

Interspersed Suggestions:
Multilevel Statement to Conscious and Unconscious

As you know enough

about phenomena

so you can let your own unconscious mind

elaborate

whatever phenomena you wish.

And in any direction.

And you should do that as an experience for yourself as a discovery of what your unconscious mind can do.

E: "Elaborate" is separated off as a separate word to make it a command.

R: What's the command?

E: "So you can let your own unconscious mind" is a permissive statement that the conscious mind hears. "Elaborate" makes it a command which the unconscious hears. It's an interspersal technique. It's not noticeable that a command has been given.

R: What's the interspersed message here?

E: The word "elaborate." The emphasis on this word changes it from just another word in the sentence to a specific word.

R: A specific direction and command to the unconscious is given with the emphasis on that word "elaborate."

Covering All Possibilities of Response to Facilitate Suggestion

Your unconscious mind can decide what part

or what aspects

of the experience should be shared by Dr. R and me.

By others in general.

By patients with whom you work.

(Pause.)

With others within you.

Also, your understandings belong to you.

But it is possible

for you to share with others in ways you never thought of before.

E: She thinks, "Should I share this with Dr. R, knowing that I know Dr. R only to such and such a degree? Is this something he can tolerate? Is this something he can be interested in?"

R: These statements are a series of psychological truisms wherein you mention all possibilities of response and thereby bring whatever she does into association with you and your words. It is easy for her to accept and follow any one of these truisms, but whatever she chooses will actually place her in the situation of following your words and thus reinforce her rapport with you and her tendency to follow other suggestions.

Depotentiating Consciousness with Boredom:
An Example of Indirect Suggestion

I'll give you a personal example.

In learning the multiplication tables at school my teacher said, "I do not know what you are doing, but you have all the answers right." I had to wait until I got to college to explain to my teacher what it was I had done.

(Pause)

I have a son whose teacher said, "Now I don't know what you are doing in your arithmetic lessons, but you do have the right answers, so keep right on with whatever you are doing."

The reason he didn't know

was that my sixth grade son was using logarithms.

This baffled the teacher.

This bewildered my son,

and he reached the conclusion that a slide rule was a child's plaything.

I sent him to a library to find some books there that might interest him.

He found a book of logarithms

and began a formal study of logarithms

and tried to teach them to his teacher.

But he really couldn't explain logarithms to his teacher,

and he later found that to teach logarithms to college students is quite a job.

I told him how I did my math.

He said,

"Well I tried that long ago, but it's too simple."

When you use multiplication tables, there is a mathematical relationship among the answers. If you know the mathematical relationship among the answers. If you know the mathematical relationship, you know all the answers.

Take the 7 times table:

7 x 1 = 7
7 x 2 = 14
7 x 3 = 21
7 x 4 = 28
7 x 5 = 35
7 x 6 = 42
7 x 7 = 49
7 x 8 = 56
7 x 9 = 63

If you know this relationship of progression in the last digit, it is easy to remember the whole table.

R: S is in a light trance at this point, so what is the purpose of giving such a complex and detailed mathematical example in such a disjointed manner? Won't this activate

her conscious mind and defeat the process of deepening the trance and unconscious learning?

E: *Often* with highly sophisticated subjects you resort to uninteresting detail to bore the hell out of them.

R: That's what you're doing here? You're boring the hell out of her? That's why you used this mathematical example! Well, you were succeeding because at that point I was also going into a trance myself.

E: They don't know what you are doing. They try to be polite, and this, past experience has taught them, can be awfully fatigu[ing.]

R: So this is a way of making her tired.

E: Yes. *Without telling her to be tired!*

R: I see. You're taking all the spunk and fire and energy out of her intellect. You're discharging it with this boredom. You're fizzling it out with boredom.

E: That's right.

R: I see! I was bored too! I was wondering, "Is this supposed to be brilliant hypnotherapy? What is this?" But now that I can see what it was used for, I can realize it's marvelous. You were depotentiating consciousness by boring it out of existence.

E: Yes. That's right.

R: This is an excellent example of your indirect approach to suggestion. You did not directly suggest she would be relaxed or tired. Rather, you had recourse to evoking a certain psychological situation or stimulus (boring arithmetic) that will arouse an internal response (acting polite) that will in turn evoke an experience of mental fatigue by associations and processes that already exist within her. She is not able to recognize the relation between what you are saying and what she is actually experiencing. Because of this the indirect suggestion escapes her conscious attention. She is responding in a certain way but may not know exactly why. This *not knowing* is compatible with the essence of trance, which is to allow more autonomous or spontaneous responses take place without the habitual sets of consciousness structuring, directing, and controlling them.

For the benefit of the reader I'll point out that I think the relationship you mean is that the last digits in the 7 times table actually form a progression that is easy to see when they are arranged in rows of three:

7 8 9

4 5 6

1 2 3

Of course, it would be hopeless for someone trying to go into trance to figure that out, so their consciousness just gives up. And that is trance when the normal ego consciousness is no longer directing and controlling things as usual.

Personal Meanings:
Discharging Negative Attitudes

Now personal meanings

to you

are yours.

The application

of all those meanings

to others

is an entirely different thing.

I could know

mathematical relationships

and couldn't explain them

to my teacher.

My son could not explain to his teacher.

But we get the same answers as they get.

We could not explain why we preferred our way.

(Pause.)

E: I'm trying to get her to understand: what may be pleasant and agreeable to one may not be pleasant and agreeable to others.

R: Why do you put that in here?

E: How many times has a patient said to you, "But you wouldn't be interested in hearing this." That's a very inhibiting thing in them. They are inhibiting themselves. You've got the task of telling them, "You are interesting."

R: You're breaking through a negative attitude of consciousness. Again you're telling S that she does not have to understand trance intellectually, she just needs to experience it.

Source of Psychological Confusion

Now the matter of hallucination,

of regression,

of time distortion,

the selection of memories,

the achieving of understandings,

the isolation of the self from a situation.

(Pause.)

I exist in the office.

(Pause.)

E: She might be intellectually interested in any of these phenomena, but she doesn't know if her unconscious wants them.

R: We have to be humble enough to let our unconscious direct and experience whichever of these possibilities it needs.

E: Yes. We let the unconscious direct. Whenever subjects, try to do what they understand [try to direct their unconscious with their conscious], they run into confusion.

R: I wonder if that throws light on the general significance of confusion when we deal with personality and inner problems? Confusion is the result of trying to impose our

conscious and more limited understanding on the broader patterns of unconscious functioning?

E: Confusion results from trying to impose some form of regimentation upon natural processes.

R: I see. That's how you would define psychological confusion.

E: A centipede can be walking along happily until some son-of-a-gun asks him which leg comes after which. Then he falls into confusion trying to figure that out. As long as the centipede does not try to rationalize, he is okay.

R: From a neuropsychological point of view, I wonder if psychological confusion and error can result from trying to impose the rational programs of the left hemisphere on the gestalt patterns of the right?

Therapist Voice Evoking Personal Associations

You can learn to hear my voice

as only meaningful sound.

Meaningful sound

to which you give the interpretation.

And it isn't necessary

for you to

waste mental energy

on the realities,

the external realities.

Now I will illustrate that.

(Pause.)

When I was demonstrating in a

hospital, I had some subjects on a stage with me.

They were not in a trance.

I told the audience that the people on stage were going to go into a trance.

While I was doing that, I noticed some people in the audience that were going in a trance.

They were very still.

I told the people in the audience they could look around and see which of them had gone in a trance. Some might have to stand up to look around.

(Pause.)

E: I want her to hear my voice as something which evokes memories and associations meaningful to her.

R: You're trying to associate your voice with meaningful dimensions within her. She can even reinterpret your words in terms of her own mental sets and personal contexts into which she places your words.

E: My words are not limited to the words themselves. They will just naturally trigger off many different associations in her.

R: So you're actually describing another natural mental mechanism here: the process of association. At the same time you're associating your voice with whatever personal associations are evoked.

E: That's right, to elaborate their associations at the unconscious level. You've already told them they don't have to share it all with you, but you do want them to elaborate.

R: You're activating the unconscious, you're getting them moving here?

E: You're getting them moving because there is a lot of territory they can cover.

R: In other words, you want patients to be active in the inner world, not just sitting there passively.

E: That's right.

Utilizing Inner Realities in Spontaneous Trance: The Common Everyday Trance

One girl in the audience stood up and looked around.

I told her she could do something she liked to do.

(Pause.)

She nodded her head agreeably.

She would do so.

I worked with the other subjects on stage.

I later asked her to give me some attention.

I asked her to tell me

if she could share it with others,

to tell me what she had been doing

and to explain it.

She said she had been down to the bay and looked all around.

There was nobody in sight so she went in swimming in the nude and had a most delightful time.

And then she heard my voice from a long distance away. A distance of 50 miles.

It was hard to recognize my voice, because of the distance, asking her to come back to the hospital room.

She came back and explained how she enjoyed swimming in the nude very much

and often swam nude alone at that place.

She had enjoyed that swim

and now felt very rested,

(Pause.)

refreshed.

(Pause.)

You have done comparable things in your dreams at night.

(Pause.)

You can do comparable things in the trance state.

(Pause.)

You can read a book.

You can go swimming.

You can converse with friends.

And everything will be totally real

because the only reality

that things possess

is the reality that our senses give them.

R: It is not unusual for you to notice the spontaneous trances that people in the audience fall into while they are apparently listening to you. Their bodies are still, they typically have a "vacant" or "faraway" look in their eyes, and their faces may be "ironed out." This sort of trance or reverie is a natural part of everyday life, and you have developed approaches to utilize these spontaneous trances for demonstration and therapeutic purposes. The very fact that this girl from the audience did stand up indicated she was in rapport with you, and your simple suggestion that she could "do something she liked to do" was sufficient to utilize her spontaneous trance for demonstration purposes.

E: When she stood up, I could tell she was in a trance by the economy of effort in her movements: a slow and highly coordinated way of moving.

R: So you utilized her spontaneous trance for demonstration purposes.

E: At an invitation by her.

R: I see. Since she did go into a spontaneous trance and followed your suggestion to stand and look around, you concluded that her unconscious was asking for a trance experience directed by you.

(Erickson here gives several other examples of how he detected the unconscious wishes of experimental subjects and patients and then utilized these wishes in deep trance to help them achieve them.)

R: This accounts for much of your success in helping subjects achieve significant objectives in deep trance. By being sensitive to what they want and need and "giving them permission" to achieve these things, they go into intense periods of inner absorption (deep trance) focused on their needs and thereby achieve their inner realization. That accounts for the potency of your clinical, patient-centered approach; you go along with the natural currents that are there striving for expression. You simply utilize what is there.

E: And when a patient says, "I don't want to do this," I say, "okay, then I'll take care of it while you do this other." So they can dissociate.

R: You help them dissociate their negative affect from something that needs to be done.

Minimal Cues and Unconscious Perception, Not ESP

A blind person

hears and feels

and smells someone else.

He cannot see that person,

but he can hear how tall a person is.

He can tell,

talking with the person,

just by his own speech to the person

he can tell if the body is male or female,

because there is a different sound bouncing off that person's body back to his ears.

He can tell if a person is facing him or has his back to him.

We all have so much knowledge.

of which we are unaware.

(Pause.)

Will you stop to think about it?

We do not know

(Pause.)

which use

of your awareness

of things

you will use.

E: Most people do not know of their total capacities for response to stimuli. They place mystical meanings on much of the information they get by subtle cues. (Erickson goes on to explain that the ability to make a subject turn around by looking at their back, for example, is achieved because the person who turns around has actually picked up minimal cues from others in the audience who have noticed the looker. If two people are alone, the same effect is achieved by detecting subtle smells or sounds of the presence of the other without even being aware that these subtle smells or sounds were utilized. On numerous occasions people have asked Erickson about the existence of ESP and other psi phenomena in hypnosis. Erickson simply replies that he has never personally encountered a situation where such "parapsychological" events could not be accounted for by minimal sensory cues which people were unaware they were capable of using.)

R: Yes, many of the mind-reading, thought-reading, and muscle-reading experiments of the early days in hypnosis (Hull, 1933) can be explained as forms of ideomotor or ideosensory cues that most people do not ordinarily recognize.

Utilizing Unconscious Cues and Perception

You can drive straight west

and pass

a distant mountainslide.

The landscape impresses you

very

warmly.

Ten years later

in driving east

you recognize that landscape.
One can think
of a situation
without using a single muscle.
Or one can think of a situation
and use only the memories
of muscle action.
Or one can very slightly
use the muscles.
One can remember
a long past fear
and be completely passive
but feel all the memories of that fear.
(Erickson here gives a personal example of memories associated with muscle action.)
And you can make my voice
just a meaningful sound
that you can interpret
in any way that you please.
(Pause.)
And you have no occasion to be
frightened
or excited
or confused
except for your own
desires
and your own
understandings.
You can look at anything
you wish
to see it.
You use your memories
to construct it.
If opening the eyes aids the construction, that's all right.
But you can construct with the eyes closed.
In brief,
there is a wide field of
exploration

for you.

[To Dr. R] Now when a patient has this opportunity to explore themselves, you are careful not to place any interpretation on anything they do.

E: This is another example of the same thing: you don't know which cues you are using, but you do remember the landscape. The whole effect is registered.

R. The whole, the gestalt?

E: Yes, the gestalt.

R: So you're telling S by this example to be sensitive to gestalts?

E: I'm telling her, "Don't assume it must be just one cue or fact that you can name in recognizing things."

R: Why are you telling her this? What are you getting at?

E: You don't know what the cues are that you are using, but you can recognize things.

R: So your unconscious is automatically identifying all those cues and ends up by telling the conscious mind, "It's so and so" without telling the conscious mind all the details of how it came to that perception. So you're telling her unconscious to utilize all its cues.

E: It doesn't have to have a cue that is nameable. The conscious mind tends to think it has to have identifiable cues, but you don't need specific cues to do things.

R: But why are you giving her this lesson here?

E: Because she's been trained as a psychologist, and one of the defects in teaching psychologists is they try to make you aware of all the cues to different things.

R: They train you to consciously label everything rather than learning to utilize your intuition (unconscious perception). With S you must undo some of this overrational training to force the unconscious to work on its own. This is necessary if she is to experience hypnotic phenomena wherein the unconscious operates autonomously. You are thus trying to activate her unconscious by (1) emphasizing all the things it does well all by itself and (2) depotentiate her over rational conscious orientation by emphasizing that it is not needed.

E: She has learned in college that you use words and numbers to express everything.

R: That rational approach is good for certain intellectual things, but for total human functioning it is not good.

E: It's *not* good!

R: It freezes you up. It limits you to your conscious awareness. It locks out unconscious perception and mentation. You don't trust your unconscious perception.

(Erickson here tells a charming story of how he and several of his male colleagues at a convention happened to be standing together watching a young female child hovering in obvious difficulty in front of a men's room. Dr. Erickson immediately wagered that she would pick the married man with the most children from among them to take her into the men's room. With unerring unconscious perception she did. The child did not stop to think, 'Now the ablest man to help me would be the one who had the most children and is therefore used to this sort of thing.')

R: So you want S to learn to trust that unconscious knowing and doing in her trance work. This experience will then help her eventually achieve a better balance between rational and irrational processes in her daily life.

E: Yes! You don't actually have to look for a wedding ring to spot a married man or woman.

Trusting Unconscious Functioning:
Trance as a Natural Form of Unconscious Functioning

[To S] We learn early that to see things we have to have eyes open. But in reconstruction of a visual scene you only need the memories.

[To R] There is that lifetime of learning that you have to open the eyes, and so you tell them they can open their eyes since it may help them.

You give them the opportunity

to open their eyes.

They also know they can

use their nose to smell

and ears to hear,

their fingers to feel.

R: They get all that by implication.

E: Yes, by implication. One can learn by reading,

by seeing,

by feeling,

by being told,

by experiencing,

and the best way of learning, to use folk language,

is by getting the feel of it.

R: *To encourage a person to go into trance you must encourage them to trust their unconscious because trance is a natural form of unconscious functioning*.

E: That's right.

R: Our view is that trance is an altered state. Do you go along with the idea that it is a paleological system of mental functioning—more on the paleocortex rather than the neo-cortex?

E: Trance is a simpler and uncomplicated way of functioning. (Erickson here gives examples of how a child learns food preferences, etc., by watching the parents and siblings reactions to food. These early learnings are based on the simpler and more direct processes of observation rather than the more complicated forms of learning involving the mediated use of words and logical thought processes that come later. Erickson does not believe, however, that trance is an atavistic state.)

Pantomime and Nonverbal Communications to Reach Simpler Levels of Behavior

You get the feel of a poem,

the feeling of a picture,

the feeling of a statue.

Feeling is a very meaningful word.

We do not just feel with the fingers,

but with the heart,

the mind.

You feel with the learnings of the past.

You feel with the hopes for the future.

You feel the present.

R: You like to use pantomime and nonverbal approaches to trance because they activate and reach in more deeply to the simpler levels of functioning.

E: Yes. You thereby bypass the enforced rigid forms of later conscious acquisitions. You don't have to have things put into words.

(Erickson gives examples in courtship. A girl may tilt her head for a kiss, but it would spoil the situation for her to verbalize her wish.)

You just ruin things with your later learnings. A tilt of the head is far more meaningful than words.

R: How can we generalize this to trance behavior as a whole? Trance is not so much regressed behavior as a simpler form of behavior—behavior that is not necessarily dependent on words and adult patterns of understanding?

E: Yes, it's awfully simple behavior.

Characteristics of Ideomotor Head Signaling in Trance

[S is making slight "yes" head-nodding motions. So slight and slow were the movements that Erickson had to silently point them out and Rossi had to carefully study S for a minute or two before he was convinced that they were really taking place. These slight "yes" responses are apparently S's expression of agreement with what Erickson was saying.]

(Erickson gives examples of the economy of body movement in trance. Nodding the head "yes" in trance is very slight and slow; this is in marked contrast to the rapid and large nodding movements to signify "yes" when we are awake.)

R: You can differentiate conscious from unconscious movements because the latter are always slower and more abbreviated.

E: If something is very important, then the movement [e.g., head nodding] will be continuous rather than just once—still slow and abbreviated but continuous so you *really* understand. They will continue the head nodding until you give some acknowledgment that you understand. Repetitive movements in trance mean a thing is more important.

Turning Problems Over to the Unconscious

Now I would leave

instruction in neurosis primarily to your unconscious.

(Pause)

And I want you to know

that in each person's life

there are things

we like and don't want to know about.

It would spoil the magicians art if you knew

how he did that trick.

How did he get that rabbit out of a hat?

Of course, there is some kind of an explanation,

but you would rather enjoy having him perform

than know how he did it.

All magicians keep their own special secrets,

and they all respect each others' secrets.

[Erickson gives several examples of how he and others have enjoyed not knowing how magicians performed their mysterious feats.]

And another thing all patients

should keep in mind,

adults are only children grown tall.

R: It seems strange to suddenly pop out with that didactic statement, "Now I would leave instruction in neurosis primarily to your unconscious." Why did you come out with that right here?

E: Because [I have prepared her for it with the previous context, where I was giving many instructions for more freedom for unconscious functioning]. So that statement would mean, "Leave *all* the instructions concerning your neurosis to your unconscious. Let us turn this problem over to the unconscious."

R: Because your conscious mind does not know how to cope with it?

E: That's right. But you do not tell them they cannot deal with it consciously.

R: Again you've taken something out of the biased, rigid sets of consciousness and given it to the more flexible system of the unconscious.

E: It would spoil the magician's art if you knew how he did that trick. If you want to enjoy swimming, do not analyze it. If you want to make love, don't try to analyze it.

R: Right, Masters and Johnson even talk about getting hung up in the "spectator" role in sex, which interferes with sexual experiencing (Masters and Johnson, 1970; Rossi, 1972b).

Facilitating Creative Perception

The unconscious is

much more childlike

in that it is direct

and it is free.

Children have asked me

why I walk that funny way

when their parents had not even noticed that I limped.

They were appalled at the children calling attention to my limp.

The children saw something they wanted an understanding of.

They were willing to reach out for an understanding.

When you have a patient in a trance, the patient thinks like a child and reaches for an understanding.

E: Patients tend to disparage themselves as being childish during trance, but don't let them disparage themselves that way. You rob them of that sort of *neurosis shelter.*

R: Self-disparagement is a neurosis shelter. So you emphasize the creative aspects of a child's fresh perception and curiosity about the world to loosen patients from their negative adult bias against natural free inquiry in trance. This is one of the characteristic ways you attempt to facilitate an attitude that will encourage them to take a fresh look at their problems from new points of view.

E: Juvenility is far superior to senility.

Protecting the Subject

Your task is to protect him.

R: To protect him?

E: To protect him so he doesn't get alarmed at what he discovers.

E: When patients came in to stop smoking, they may say when in trance, "I don't really want to stop smoking." The therapist then sees physical alarm; they now know the truth about themselves. So you say to them, "I don't think you should know that when you're awake *yet."* You protect your patient. You're protecting the conscious mind by keeping that self-understanding unconscious.

R: Because the conscious mind should not have its sets shattered too rapidly.

E: Yes, that can be a shattering experience unless the patient has the strength to endure it.

Lies in a Trance

An example is in lying. Children are entitled to tell lies. They are entitled to see things as they are without being frightened.

E: When a person in a trance says something you know is a lie, you better look it over because it has another meaning.

R: It has meaning other than being a lie?

E: Yes. In some way the person is telling the truth. A truth as seen from a totally different point of view. And bear in mind that you as the therapist also have your own set and rigid points of view to deal with.

R: Would lies in a trance also be an indication of regression to a more childlike state?

E: It's a regression to a more simple mode of functioning, less complicated. A person may tell you of going to a circus in Wisconsin, yet they have never been to Wisconsin. That may mean they are identified with somebody in Wisconsin. This is their way of telling you about an identification when they don't have a vocabulary to permit them to say, "I identify with so and so."

R: They express an identification by attributing something about the other to themselves. This kind of psychological language accounts for many of the so-called lies and distortions expressed in trance.

Conscious and Unconscious as Separate Systems

A child will drop a glass on the floor and say with wonderment, "It broke!"

And not necessarily have to react with adult understanding that it was a valued antique.

(Pause.)

Every patient needs to know that the emotional content of something can be experienced with no knowledge of what caused the emotion.

(Pause.)

A patient can also recall the intellectual memories of an event as if they happened to someone else.

Many other things have no meaning to the self, and then later the emotions and intellectual content gets together

piece by piece, like a jigsaw puzzle.

E: It's well to let them experience this state of wonderment in the trance.

R: That would mean that in the trance state their unconscious is free from the biases of the conscious mind?

E: Yes. It shows the unconscious can forget what the conscious mind knows. It may leave certain knowledge in the conscious mind.

R: I see. So the conscious and unconscious really are separate systems?

E: Yes, they are separate systems.

R: Do you have any therapeutic goal for the ideal mode of psychological functioning? A certain amount of interchange between the conscious and the unconscious, for example?

E: The ideal person would be one who had a readiness to accept the interchange between the conscious and unconscious. Children are uncluttered by rigid conscious sets, and therefore children can see things that adults cannot.

Right- and Left-Hemispheric Functioning in Trance

I taught my sons the best way of hoeing a garden.

You have a square yard at

the northeast corner,

a square yard at the northwest corner,

and then the southeast and the southwest.

Now that you have hoed a square yard at all corners, you hoe a square yard in the center. Then hoe a line from the middle to a corner.

Now you're making a design of the garden.

That is a very interesting way of doing a laborious piece of work. You become so interested in the design that it's a pleasure.

In working at a problem of difficulty, you try to make an interesting design in the handling of it.

That way you have an answer to the difficult problem.

Become interested in the design and don't notice the back-breaking labor.

In therapy that is often a very delightful thing to do.

(Pause)

When you do work freely and willingly,

one has a right to take a rest period at any time.

You are free to resume work at any time.

Free to alter the design and pattern in which the work is done.

One can do automatic writing from right to left or left to right.

[Erickson here gives a detailed clinical example of a child who wrote backwards and upside down and from right to left but not the conventional way. Rather than attempt to correct the child by prohibiting his unusual ways of writing, Erickson pointed out to the child his superiority in being able to write in three different ways while Erickson could only write in one: the conventional way. Erickson then proceeded to try to learn to write one of the ways the child did, and the child, to maintain his superiority, now wanted to learn yet another way of writing—the conventional way. He was now learning his fourth way of writing while Erickson was still struggling to learn his second.]

E: Another simple technique of distracting consciousness from a laborious piece of work.

R: So here again in this lengthy example you're telling S to let go of her conscious sets and orientation because they are so laborious. You are suggesting that she substitute a kind of creative, aesthetic play with patterns for the hard work of hoeing in laborious linear rows.

Throughout this and many previous sessions many of your efforts could be understood as distracting or depotentiating the linguistic, rational, linear, and directed modes of left-hemispheric functioning in favor of the spontaneous perceptual-aesthetic, kinesthetic, and systhetic modes of right-hemispheric functioning. Dream, reverie, and trance have recently been characterized as right-hemispheric functions. When you emphasize trusting natural or unconscious patterns of functioning in trance, you are actually emphasizing the paralogical or appositional (Bogen, 1969) characteristics of the right hemisphere. It may well be that future research will establish that much of what we have until now characterized as the dichotomy between the conscious and unconscious (secondary and primary process thinking) is neuropsychologically a dichotomy between left- and right-hemispheric functioning. From this point of view many psychological problems could be understood as the erroneous imposition of rational left-hemispheric approaches to situations that could be better dealt with by the right hemisphere.

Training the Modern Mind to Rely on the Unconscious

Now the next thing I want to say to you is this: It is never necessary when you sleep at night to remember your dreams the next day.

It's possible to dream tonight

and wait a year before you remember

the dream.

You may remember a part of the dream

tomorrow and part of it next week.

Your remembering the dream

has to be in accord

with what you need.

You don't have to remember.

The important thing is to have

certain experiences

recorded in your mind.

Some day their presence will be of service to you.

It is necessary for you to be aware

that you know they are there.

The important thing always is

to do the right thing at the

right time.

To know that you can rely on yourself.

To let your unconscious feed to you

the right information that permits you

to do the right thing at the right time.

It may be this year or

next year

or two years from now.

(Pause)

> R: You are again illustrating the unimportance of consciousness relative to the unconscious in trance. With all these examples you are telling S that she can rely on her unconscious. This approach is needed with S because she is, relatively speaking, a highly intellectualized person with a Ph.D. This approach of retraining the patient to rely on the unconscious is going to become more important in the future as more and more people become highly intellectualized. Direct authoritative suggestions may have been appropriate 100 years ago, when it was possible to reach the unconscious that way. But the modern hypnotherapist has to help people relearn that natural mode of functioning where they leave things to their unconscious.

Indirect Posthypnotic Suggestion

An illustration is when you awaken. One of the most pleasant things you have to experience is in coming out of the trance

thinking you are ready to go into a trance

for the first time.

And then becoming aware that you must have been in a trance.

Maybe the degree of light outside indicates that.

The indication is from the outside.

That can be assessed by you

as a beautiful learning experience.

(Pause)

R: This is an example of an indirect posthypnotic suggestion. First you carefully lay the groundwork by talking about forgetting dreams until it is the right time to remember them. You thereby hope to evoke forgetting mechanisms. Just as she can forget a dream until it is important to remember it, so can she, by implication, forget she was in trance until it is important to remember it. You then administer the indirect posthypnotic suggestion. You don't directly tell her to forget she was in trance. That might only evoke the typical reaction of consciousness, "But I don't know how?'" Instead, you describe the kind of pleasant experience she can have "coming out of the trance thinking she is ready to go into a trance for the first time." Instead of giving a direct suggestion to do something consciousness would find difficult, you simply motivate her for a "pleasant" experience. You talk about the degree of daylight outside as an indication of the passage of time. Perhaps that will be the only cue that will enable her to recognize she was in trance for some time. You also prepared for this earlier when you talked about the way the unconscious uses cues and the value of relying on the unconscious to do things.

Thus, during the earlier part of this session you were laying an important foundation for this seemingly casual posthypnotic suggestion. You were building an associational network and activating mental mechanisms that might be utilized to facilitate forgetting in an entirely autonomous or dissociated manner.

E: Yes, you are always building one thing on another and relating what you are saying now to what you said earlier.

Depotentiating Consciousness: Analogies of Lapses in Consciousness

In everyday life

you overhear people saying to themselves,

"Now just how did I do that?"

What they mean is,

they don't know how they did it.

They have only an incomplete view of how they did it.

They then have to recover

step by step

the manner in which they did it.

R: Experiencing and learning come before understanding.

[Erickson here gives several clinical examples of how he recognized minimal cues of hand, eye, and lip behavior that indicated that certain patients did not really want to give up smoking even though they presented themselves in therapy for that purpose. These examples illustrated the difference between conscious purpose and a deeper understanding of motivation.]

R: Here you're giving examples of lapses in consciousness in everyday life. By simply mentioning these possibilities you hope to facilitate their occurrence in S as a means of depotentiating her consciousness so she can learn to rely more on her unconscious.

Accepting Spontaneous Awakening

[Much of the above actually appeared to be a conversation between Erickson and Rossi. S apparently felt abandoned and began spontaneously to awaken, as was

indicated by minimal movements of her lips, nose, forehead wrinkling, and some finger movements. Erickson notes this and remarks that she is awakening and getting ready to talk to us.]

S: What do you want to know?

E: Only what you want to tell us.

S: Well, I was jumping around a lot. When you were saying I was trying to wake up, I actually had already abandoned the idea because my hands were so heavy I couldn't move them. But when you said I was waking up, I tried to wake up again. But I'm kind of curious why you don't follow through with someone who is in trance. Like when I do hypnotherapy, I stay right with the patient the whole time, and then when I judge it's right, I say you can count to wake up or whatever. Why don't you do something like that?

R: Yes, Dr. Erickson, why don't you behave like a regular hypnotherapist should?

R: Here you accepted her spontaneous awakening and utilized it as part of a hypnotic suggestion by simply remarking on it and helping it happen further. People are continually going in and out of trance, so when they are coming out you may as well utilize that behavior to strengthen the hypnotic relationship rather than contesting it and setting up a battle of wills between therapist and patient. You can be with them whether they are in or out of trance.

E: You may as well join them when they come out, and later they will join you in following your suggestions more easily. You always give the patient approval for what she is doing.

R: There is no need for the beginning hypnotherapist to panic when a patient spontaneously comes awake. That's just their natural mode of functioning and is to be accepted as a way of strengthening the hypnotic relationship.

E: If it is their way of functioning, you'd better go along with it.

R: *The therapist is not really in control of anyone*.

E: That's right!

Alternating Rhythms of Suggestibility

R: There are only moments when the therapist can effectively direct something the patient wants to experience. But it is "touch and go—touch and go." Moments when a suggestion can be accepted alternate with moments when they cannot.

E: And the therapist can remain comfortable in that situation.

R: Yes, this is very important for the beginning therapist to learn: there is a natural rhythm in patients that the therapist learns to recognize and go along with. 1 used to get all tense in working with patients by thinking, "Oh, this is not working, that doesn't work either, the whole thing's not happening." Such an attitude I now see is ridiculous.

E: It is so ridiculous! You never give the patient the impression that you must be constantly alert. You give them the impression that they are always sharing in the responsibility for the success of the work. S had expressed her belief that when she did hypnotherapy she had to stay right with the patient all the time. Therefore when I appeared to be distracted, that gave her reason to wake up.

Trance Training and Utilization

S: What is the logic of what you do?

E: In a learning situation you have to do your own learning. I want you to learn a lot faster than I did. It took me about 30 years to learn, and there is no sense in that. Now if I were treating you for a problem, I'd stay with you and give you support at different points. But you are in a learning process, getting the feel of everything.

S: But this way I just trip around till I'm bored and then come out of it.

E: Are you sure you come out of it because you are bored?

S: It's almost as if I fell asleep because I caught myself nodding a few times.

What was happening on your left side, some distance off to the left? Were you looking for something?

[Erickson now puts a detailed series of questions to S regarding the subjective experiences that were associated with her behavior in trance, such as eye and head movements to the left and right, minute movements of the face, breathing alternations, etc. In an amazing way Erickson revealed he had actually observed many more details of S's trance behavior than she could recall.]

R: With this question S reveals her highly rational approach. That is why you've spent most of this session telling her to give up consciousness control. Could you elaborate here on just what you want her to learn on her own? This appears almost like self-hypnosis, where the person has to do it all on their own. You're telling her to learn to let things happen?

E: That's right.

R: If an itch happens, fine, go along with it. If heaviness happens, fine, go along with it. If memories happen, fine! If you flash and trip around in your head, fine!

(Erickson here tells an amusing anecdote about a husband and wife trying to outdo each other in growing tomatoes. A few days after planting them the wife decided they needed more sun, so she transplanted them. Later it seemed to her they needed more shade, so she transplanted them again—and so on. She was still transplanting them when her husband was harvesting his tomatoes.)

R: So what's the relevance of that story for what we are discussing?

E: You let the subject grow!

R: Oh, they learn to do their own thing at their own pace. You let them grow and not interfere with their natural growth process.

E: *My learning over the years was that I tried to direct the patient too much. It took me a long time to let things develop and make use of things as they developed*.

R: That accounts for your development of utilization techniques—one of your basic contributions to modern hypnosis. You utilize the patient's own behavior to initiate trance, self-exploration, and the like.

Failure of Suggestion by not Meeting Patient's Needs

S: When I tried to lift my arms toward the end in an effort to awaken, I got dizzy.

E: Why do you think you got dizzy?

S: It was like when you first wake up in the morning and you are very groggy. It was a disorientation, as if I could be tipping all sorts of ways. It was a strange body sensation. ... I was myself enjoying the trance in the beginning; then I became the therapist, wondering why the heck you weren't telling me what to do.

R: I think S has been getting impatient with us.

E: Impatient in a curious way, and that is always a barrier.

S: Well, I guess I want to know the practical things about hypnosis: what it is, how you deal with problems, how you deal with smoking, weight problems, etc.

R: S is used to intellectual learning rather than the experiential learning of trance.

[Erickson terminates this session by giving several examples of experiential learning and knowing versus intellectual learning.]

> R: You attempted to extend her trance training in this session by giving her an interesting posthypnotic suggestion to forget she was in trance. To carry out that suggestion successfully, she would have to rely on her own unconscious, as she did in her last session when she experienced that marvelous age regression, hypermenesia. But in this session she was irritated because you did not meet her preconceived expectations of how closely attentive you should be to her during trance. Because these more personal emotional needs were not met, your indirect posthypnotic suggestion paled into insignificance and was not received. That she was experiencing trance is indicated by the heaviness of her hands, but then the therapist observer within her may have gotten in the way of further experiential learning in this session. This is a clear indication of how important it is to recognize and meet in some way the patient's emotional needs before we can expect them to relax to the point where they can rely upon their unconscious to carry out suggestions.

TRANCE TRAINING AND UTILIZATION

Erickson makes a highly significant statement in this commentary, "My learning over the years was that I tried to direct the patient too much. It took me a long time to let things develop and make use of things as they developed." This entire session with S was an effort on Erickson's part to train her to allow things to happen spontaneously, unconsciously. The most basic learning in hypnotic work is to let things to happen of themselves, to let the unconscious function as free as possible from the learned habits and programs of consciousness.

It took Erickson a long time to learn that this is the first essential in all sound hypnotherapeutic work. Patients are patients because they are out of rapport with their own unconscious. Trance allows the patient to experience his own unconscious free, to some extent, from the limitations of his conscious sets. Once this unconscious mode of functioning becomes manifest, then Erickson feels free to help the patient utilize it for therapeutic purposes.

Therapeutic hypnosis is not just another technique for programming patients. Patients are people who have had too much programming—so much outside programming that they have lost touch with their inner selves. Therapeutic trance is an experience wherein patients receive something from within themselves. The astute hypnotherapist is one who arranges circumstances to permit such receptivity to inner experience. He helps the patient to recognize the value of his unique inner experience and provides suggestions about how it may be utilized therapeutically.

We may note that this way of defining therapeutic trance is very similar to the classical use of meditation. The word "meditation" comes from the Latin *meditari,* a passive form of the verb that means literally "being moved to the center." Consciousness remains passive as it is moved to the center (the unconscious), where it can achieve wholeness: a reunion with contents and tendencies that have been excluded from consciousness (Jung, 1960).

THE DYNAMICS OF INDIRECT AND DIRECT SUGGESTION

Erickson's use of a boring explanation of arithmetic to fatigue Dr. S in this session reveals some basic principles of his use of indirect suggestion in a particularly clear manner.

Erickson did not directly suggestion that she would be relaxed, tired, or fatigued. Rather he used an arithmetic explanation as a stimulus ($S_{arithmetic}$) for evoking an external response of being polite (R_{polite}),which in turn evoked within Dr. S an internal response of boredom ($r_{boredom}$) which led her to feel fatigued ($R_{fatigue}$). This process of outer stimulus, internal mediation, and behavioral response can be outlined as shown in Figure 1. There is little or no identity between the suggestion ($S_{arithmetic}$) and the final response ($R_{fatigue}$) that the subject can recognize or influence in any way.

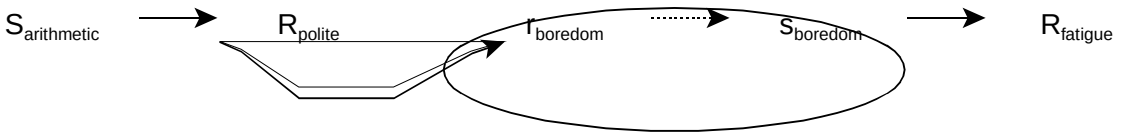

Figure 1. The process of indirect suggestion with no obvious relation between the suggestion (Sarithmetic) and response (Rfatigue)- The large letters represent overt, external, objective events, while the small letters (r and s) represent covert, internal, subjective events that are usually not understood or even recognized by the patient.

Direct suggestion, by contrast, presents subjects with a stimulus that identifies what the response should be. Frequently the therapist offering direct suggestions will actually tell subjects exactly what internal processes they should use to mediate the response. In giving a direct suggestion the therapist can only hope the subject will cooperate with this exact suggestion or find other internal processes by which the response can be mediated. How the response is mediated within is sometimes understood at least in part by the subject. When they are successful, subjects usually report that they imagined themselves in a fatiguing situation, for example, and then by association they managed to evoke a response of fatigue they could actually feel. Some investigators (Barber, Spanos, and Chaves, 1974) actually train their subjects to use conscious ideation in this way. Direct suggestion could be diagrammed as shown in Figure 2, where there is a clear identity between the initial suggestion, the internally mediated responses, and the outer response that the subject can recognize and influence.

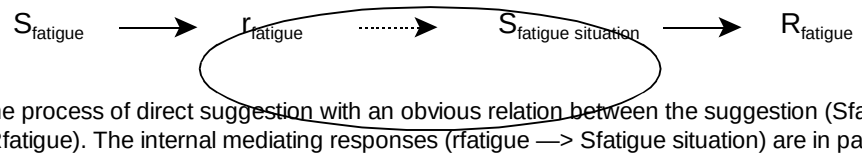

Figure 2. The process of direct suggestion with an obvious relation between the suggestion (Sfatigue) and the response (Rfatigue). The internal mediating responses (rfatigue —> Sfatigue situation) are in part recognized and understood by the patient.

Direct and indirect suggestions can both achieve effective results, but they are mediated in different ways such that their relations to consciousness and volition are different. Direct suggestion is mediated by internal processes that the subjects usually have some awareness of. The subjects recognize that they made the response happen. The response is more or less under voluntary control. Indirect suggestion, by contrast, is usually mediated by internal processes that remain unknown to the subjects. The response, when it is noticed, is usually acknowledged by the subjects with a sense of surprise. The response appeared to occur in an involuntary and spontaneous manner. It has a curiously dissociated or autonomous aspect that is usually acknowledged as "hypnotic."

A problem with direct suggestion is that the responses obtained may simply be voluntary compliance on the part of the subjects. They may simply be trying to please the therapist in a fully conscious way. Thus, theorists who have identified hypnosis and trance with suggestibility (compliance with direct suggestions) have been led to a downgrading of the autonomous or involuntary aspects of hypnotic experience. Thus, we have theories of trance as voluntary role-playing (Sarbin and Coe, 1972) or a form of voluntary conscious cooperation in thinking and imagining along with the theorist's suggestions (Barber, Spanos, and Chaves, 1974). These are all actually theories of direct suggestion. An unconscious or

involuntary component is not necessarily evident when a subject accepts and acts on a direct suggestion.

With indirect suggestion, however, subjects usually do not recognize the relation between the suggestion and their own response. There thus can be no question of voluntary compliance with the therapist's suggestion. If a response does take place, then it has been mediated by involuntary processes outside of a subject's immediate range of awareness. This involuntary mediation of responses is what we use to define the genuineness of trance behavior. The involuntary or autonomous response that surprises consciousness is what differentiates hypnotic from ordinary awake behavior. Such autonomous responses can be elicited by direct suggestions—(e.g., all the suggestions of the Stanford (Hilgard, 1965 and the Barber et al. (1974) hypnotic suggestibility scales—but with direct suggestion there is always the problem of simulation: Did the response take place in a voluntary or involuntary manner? With indirect suggestion, however, the very appearance of a response can be a satisfactory criterion of its involuntary nature, since the subject is unaware of why or how it happens.

Weitzenhoffer (1957, 1974, 1975) has emphasized that the defining feature of hypnotic suggestion is the absence of conscious volition in the production of the hypnotic response. We agree with this basic formulation. In order to take a preliminary step in making a distinction between direct and indirect suggestion we have discussed the role of conscious awareness and intention in our formulation above. In direct suggestion it is possible for the patient to have some conscious awareness of how the hypnotic response is mediated within and may in consequence attempt either to inhibit or to facilitate the hypnotic response with conscious intentionality. With indirect suggestion care is taken so that the typical patient will not become aware of how the hypnotic response is mediated within; hence there is less opportunity for conscious intentionality either to facilitate or to block the response.

INDIRECT CONDITIONING OF TRANCE

Erickson's use of indirect eyelid conditioning in this session is another prime example of his indirect approach. He labels a slow eye blink (associated with trance) with the word "odd" and a fast eye blink with the word "even." The subject did not know the connection between her eye blinks and the words. An association can be made between the rapidity of eye blink and the words "odd" and "even" without conscious awareness. Once this association is made, then saying the word "odd" will tend to evoke slow eye blinks, and since slow eye blinks are associated with the beginning of trance (by previous eye fixation induction as well as by everyday life experience wherein we do begin to blink slowly as we drift into altered states like daydreaming and sleep), subjects find themselves drifting into trance without knowing exactly why.

Erickson actually uses many forms of indirect or incidental conditioning that take place all by themselves. Often he relies on nothing more than the natural processes of associational conditioning that are formed between trance experience and the situation in which the first trance occurred. Subjects who have successful experiences with trance the first time they come into Erickson's office will have many associative connections built between trance experience and Erickson as a person, his voice, his manner, and other characteristics. There will be associative connections between trance and the subject's presence in the office and sitting in the same chair as the first time. There will be associations between the appearance of the room, the presence of the cut-glass paperweight that Erickson usually uses as a point for eye-fixation induction, etc. Indeed, for some subjects the simple behavior of going to an appointment with Erickson is enough to initiate the expectation of trance so that inner adjustments are being made to facilitate the trance experience even when the subjects are on their way to an appointment.

Erickson simply watches for these natural processes of conditioning the experience of trance. When patients enter the office, Erickson carefully observes their behavior for the subtle signs of trance. Many of these are standard signs that are fairly applicable to most people: slow eye blink, economy of movement, smoothing of facial features, response

attentiveness, and so on. Some signs are characteristic of an individual: a part of the body held in an inconspicuous catalepsy (e.g., the finger of one hand bent in a characteristic way), a particular gaze or manner. When Erickson sees these signs of naturally conditioned trance behavior emerging, he simply adopts his own usual manner when inducing a trance. He will look at the patient with his characteristic attitude of expectancy. He may look meaningfully at the cut-glass paperweight. He might take a deep breath and visibly relax. He might even close his eyes for a moment. These are all nonverbal cues for patients to enter further into the trance they may already be experiencing. Patients are surprised to find how easily trance develops, and they frequently have no idea of how or why. Even when patients have some intellectual awareness of how they have been conditioned to experience trance, they find it more comfortable to go along than to resist. Yet, if patients want to resist the developing trance, they certainly can. Such indirectly conditioned trances develop to a significant degree only in an atmosphere of trust, comfort, and cooperation, where there is an expectation that something will be gained from the experience.

Exercises with Indirect or Incidental Conditioning of Trance

1. Learn to observe your patients carefully as they enter the therapy situation after having had a trance experience during the previous session. Can you discern signs of developing trance?
2. Carefully study your own physical office situation and induction procedures to discover what incidental associations are being formed between your patients' trance experience and the physical characteristics of the setting and your own behavior. Plan how you might utilize these to facilitate later trances.
3. What nonverbal cues can you learn to utilize to reinduce trance in your previous subjects? Many of these will be the slight alterations in your own behavior as you are facilitating trance experience in your subjects. It may help to have a trained observer present to help you recognize subtle behavior changes that you do not recognize yourself.

VOICE DYNAMICS IN TRANCE

Erickson's use of voice dynamics is another major approach to indirect suggestion. This use of voice dynamics ranges from simple direct suggestion that his voice will evoke personal associations to indirect conditioning wherein he associates the locus of his voice to different processes within the subject.

Alternating Attention to Therapist's Voice as an Indication of Trance Experience

In the traditional style of direct suggestion the therapist often tells the patient to pay attention to the therapist's voice and ignore everything else. That is an effective approach with direct suggestion. For indirect suggestion, by contrast, Erickson will typically tell patients that they do not have to bother listening to his voice. When patients later report that during trance they lost track of Erickson's voice and did not always know what he was talking about, it can be taken as an indication of the typical development of trance. Initially many subjects report an alteration in hearing and not hearing or paying attention. This spontaneous alteration may correspond to the spontaneous alteration of trance depth that is a characteristic feature of hypnotic experience.

Therapist Voice as Vehicle for Projection

In this session Erickson suggested that Dr. S could learn to hear his voice only as a meaningful sound to which she would give an interpretation. That is, the content of Erickson's words could be ignored. The sound of his voice could become a vehicle carrying Dr. S's own projections. Frequently Erickson will suggest or imply that what he says is not important. Only the patient's interpretation of what he says in important. Because of this he will use words with multiple meanings, puns, incomplete sentences, and dangling phrases, so that the patient's unconscious can project meanings that are important to itself.

Voice Locus and Volume for Spatial-Perceptual Associations

One of Erickson's unique contributions to the use of voice locus is what we might call its spatial-perceptual associations. As he talks about associations and memories back in the past, he may tip his chair backward away from the patient, lower his voice, and even turn his head away from the patient, so that it seems as if his voice is coming from far away. Just as the voice is far away, so will the patient's memories come from far away in their dim past. As those memories stir and become available to the patient's awareness, Erickson may gradually tip his chair forward and come closer to the patient and speak more clearly and loudly. But his manner is always subtle, so that the patient does not recognize what he is doing.

The patient's unconscious, however, may utilize these differences in voice locus and volume as stimuli that evoke altered patterns of association that may make valuable memories available. In one striking demonstration with a subject who was visualizing a suggested scene with her eyes closed, Erickson would raise the pitch of his voice and actually project it upward by looking up when he wanted her to see something up in the air and vice versa when he wanted her to see something lower on her internal visual screen. The movements of her closed eyes were observed to follow the locus and pitch of his voice exactly. The patient later remarked about the peculiar alteration in the height at which the suggested images appeared to her. Erickson (1973) has reported how voice locus can be used to induce sea sickness, vertigo, and similar conditions.

Voice Locus for Conditioning Conscious and Unconscious Levels of Receptivity

One of Erickson's most interesting but controversial uses of voice locus is his effort to direct suggestions selectively to the conscious and unconscious of the patient. As he goes through his induction talk, Erickson may shift slightly to the right every time he mentions the word "conscious" or talks about obviously conscious matters of interest. He shifts slightly to the left whenever he uses the word "unconscious" or talks about involuntary and autonomous processes that are usually mediated without voluntary conscious control. Without the patients realizing it, they are being conditioned to associate conscious voluntary processes with voice locus coming from the right and unconscious or involuntary and disdissociated processes with voice locus on the left. Once these associations are established, Erickson can beam a suggestion to a conscious or unconscious level by shifting his voice in the appropriated direction. It will be a matter of future empirical research and practice to determine the effectiveness of this procedure and the degree to which others can learn to use it effectively in a systematic way.

Exercises with Voice Dynamics

1. Study tape recordings of your own voice during therapy sessions and in everyday life situations to become more familiar with your own natural voice dynamics in different circumstances and what you are consciously and unconsciously communicating.

2. Study recordings of your voice before and during trance induction to learn what changes you usually make and how these changes may be facilitating or interfering with trance development in your patients.

3. The actual conscious utilization of one's own voice dynamics requires some practice. The object is to use voice dynamics in a way that does not arouse the patient's conscious attention. Otherwise their purpose may be largely lost. One can begin by learning to speak a bit *softly* when one wants to obtain the listener's closer attention. One can then learn to speak more *slowly* when one wants to help a listener slow down. One can practice speaking just a bit more loudly and distinctly when one wants a patient to arouse from trance.

4. Explore the use of voice locus in conditioning subjects to receive suggestions at different levels of awareness. Can you devise new field experiments (Erickson, 1973) or more controlled experimental situations to assess the effectiveness of this use of voice locus?

INTERCONTEXTUAL CUES AND INDIRECT SUGGESTIONS

The lengths to which Erickson will go in utilizing all sorts of inter-contextual cues as indirect suggestion is indicated in the following dialogue.

Erickson: I had some repetitive dreams last night about some things that should be said about this. In giving suggestions and instruction to hypnotic subjects in the trance state, it is not only what you say, but it is what they hear, that is important. I can give you an example.

Let us say there is a village named *Sunflower* in Arizona. Let us take another imaginary place we will call Weldon's *ditches.* You carry on a casual conversation about Arizona and you mention *Suntower.* Rather than *Sunflower.* You purposely say *Suntower.* The person listening automatically and unheedingly corrects you and doesn't know that you actually said *"Suntower."* In talking about the southern part of Arizona and strip mining you mention Welson's *Britches* (instead of *Ditches).*

Now you have said two things outrageously wrong and the subject has consciously corrected what you said. So consciously they think you said *Sunflower"* and Weldon's Ditches. But the unconscious heard you say *Suntower* and *Britches.* They detect and remember that. You can later use that because they don't know why they are impelled to talk about a *flower* and a Dutchman's *Britches.*

Rossi: They are impelled to use those associations which you placed in their unconscious.

Erickson: Yes. They may then talk about that "Devils Tower" in the Caribbean and have no idea of how you got that association across to them. But you know how you have done it. They can't consciously ever figure it out. Their consciousness corrected for their conscious mind, but their unconscious heard it.

Rossi: Your error remains lodged in their unconscious, striving for expression.

Erickson: It is lodged there in the unconscious, and you can keep on talking and drive the conversation in such a fashion that the discussion of wildflowers brings up Dutchman's *Britches* and the Devils *Tower* in the Caribbean.

This rather extreme example may be characterized as one of placing associations within the patient's unconscious and then allowing the unconscious to utilize them in its own way. A more common practice is Erickson's habitual use of pauses that break up his sentence structure into phrases, each of which can have its own meaning that can be entirely independent of the meaning the sentence has as a whole. In our transcripts of the induction

section of each session we made an effort to note these important pauses. The separate and independent meaning of each phrase can be described as intercontextual cues and suggestions that are picked up and partially processed by the unconscious, while the conscious simply waits for the remainder of the sentence. These phrases buried in the context of the sentence thus function as another form of indirect suggestion.

This use of phrases as separate suggestions buried within the broader context of the whole sentence is actually another form of *interspersal technique* (Erickson, 1966b). Erickson has illustrated the uses of *interspersing suggestions* within the broader context of a general conversation about a topic the patient can easily identify with (e.g., a general conversation about growing plants with a farmer, caring for children with a mother, and so on). Interspersed in this conversation is a pattern of suggestions that come at random intervals (frequently with a slightly different intonation of voice) so they are unpredictable by the subject. The interspersed suggestion comes at an *unexpected moment,* it is *short,* it is usually a *truism* that is not arguable, and the therapist *quickly moves on* to the general conversation before the patients can react to the suggestion. The suggestion is received, but the patients have no opportunity to resist it with their habitual associations, limiting frames of reference, or other inhibiting factors.

The general conversation that is of interest to the patients has the following functions as a vehicle for the interspersed suggestions.

1. The general conversation facilitates the development of an accepting or "yes set," since it is a topic of interest to the patients. The interspersed suggestion is thus received with acceptance along with the overt message that is motivating to the patients.
2. The general conversation keeps the patients "awake" at an optimal level of receptivity rather than drifting to the border of sleep and its uncertain receptivity.
3. The topic of interest facilitates patients' rapport with the therapist, rather than have them drift too far off into their own associative matrix, which might again result in uncertain receptivity.
4. The interspersing of suggestions within a familiar and redundant message facilitates a *structured amnesia* (Erickson and Rossi, 1974) for the interspersed suggestions and thus prevents a patient's usual associative structure from interfering with the suggestions.

The *intercontextual cues and suggestions* buried within the general context of a *sentence* would appear to function in the same way as the *interspersed suggestions* in the context *of a general conversation* as described above.

Exercises with Intercontextual Cues and Suggestions

1. Review the induction sections of all previous sessions to study the intercontextual cues and suggestions that are present in the phrases but not in the sentence as a whole.

2. On the other hand, note how at times the separate phrases of each sentence have the same implications as the total sentence. In such cases the phrases can summate and greatly reinforce the suggestion contained in the sentence as a whole, but without belaboring the point and possibly arousing the limiting reactions of an awakened consciousness.
3. Notice how often in previous commentary sections Erickson brings attention to this or that phrase as a separate suggestion buried within a more general context. It wasn't until this session, however, that it finally dawns on Rossi that Erickson was trying to teach another indirect approach to suggestion, which we have now labeled "intercontextual cues and suggestions."
4. In actual practice it is very easy to learn how to administer inter-contextual cues and suggestions. Simply tape record your sessions and later study the transcripts to note what intercontextual cues and suggestions you are unwittingly giving. As you become more sensitive to your own buried suggestions, you will develop a heightened awareness of what you are saying when you actually say it in the therapy sessions. Soon you will welcome the pauses in your sentence structure to savor your intercontextual cues and bring them under

greater control. As you administer a phrase and carefully watch the patient's face, you can study the patient's involuntary response (wincing, smiling, etc.) to each separate phrase. This can give you a sense of the reality of intercontextual suggestions. You will then be able to utilize these immediate patient responses as a kind of feedback to make you more aware of the effect your words are having on the patient's associative structure. You can then learn to orchestrate your phrases and the patient's responses to more adequately effect the therapeutic harmonies you are attempting to create together.

RIGHT- AND LEFT-HEMISPHERIC FUNCTIONING IN TRANCE

In our efforts to conceptualize Erickson's understanding of trance and its facilitation we have used a number of different models:

1. The psychodynamic model of the conscious-unconscious system
2. The learning theory model of behavioral psychology
3. A linguistic model utilizing multiple levels of communication.

From this session it is finally clear that a neuropsychological model utilizing the differences between right- and left-hemispheric functioning is also implicit in Erickson's work, even though he developed his views and skills long before the recent studies of hemispheric functioning (Sperry, 1968; Gazzaniga, 1967; Bogen, 1969). These studies suggest to some investigators that experiences of trance, reverie, and dream are all characteristic of right-hemispheric functioning, while the rational, logical, and verbal modes of functioning are more characteristic of the left. A summary listing of the differences in hemispheric functioning that can be related to Erickson's emphasis on the differences between awake and trance experience is as follows:

Left Hemisphere (Awake)	*Right Hemisphere (Trance)*
Linguistic	Pantomime, kinesthetic, musical
Logical-Grammatical	Visuospatial
Rational	Intuitive
Abstract	Literal-concrete
Analytical	Perceptual-synthetic
Directed	Spontaneous
Focal	Diffuse
Effort	Comfort

From this dichotomy it is clear that much of Erickson's efforts to facilitate trance experience are directed to depotentiating left hemispheric functioning. The hallmark of left-hemispheric functioning is the linguistic and logical-grammatical organization of consciousness, which is usually related to the location of the speech center in the left cortex. Many of Erickson's nonverbal, pantomime, and indirect approaches to trance induction are obviously means of shifting consciousness away from this linguistic specialization of the left hemisphere. As we have discovered in this volume, many of Erickson's habitual forms of verbal expression are actually designed to jam or depotentiate the orderly, rational, abstract, and directing functions of a subject's usual modes of left-hemispheric knowing. His use of shock, surprise, dissociation, shifting frames of reference, confusion, paradox, and double binds are thus all directed to depotentiating the left hemisphere. His emphasis on body language, cues from voice locus, emphasis, rhythm, etc. are all shifts away from the rational and analytic to the perceptual, kinesthetic, and synthetic of functioning so characteristic of the right hemisphere. When he uses hypnotic forms like implication, expectancy, partial remarks, and dangling phrases, analogies, metaphors' puns, and folk language, he is again shifting away from the abstract and analytical to the intuitive and synthetic modes of the right. Many of the most characteristic features of trance experience such as reverie, dream,

literalism, comfort, and the autonomous or spontaneous flow of mental experience and behavior are all facilitated by hypnotic forms such as not doing and not knowing, open-ended suggestions and suggestions covering all possibilities of response.

Many investigations (Bakan, 1969; Morgan, MacDonald, and Hilgard, 1974) have explored the view that left-hemispheric functions are diminished during trance and then assumed that right-hemispheric functioning was thereby enhanced. This does appear to be the case in those specialized trance states where there are suggestions made to enhance patients' perceptions of their own body and personality. The right hemisphere is more directly concerned with the perception of sensory and kinesthetic cues, spatial orientation, and the organization of the body schema (Luria, 1973). In the more typical trance state, however, it is precisely the disturbances of the body schema that we recognize as characteristics of the trance state. Distortions of the body image—such as feeling a part of the body (head, hand, etc.) as being unusually large or small, dissociated, or anesthetic—are frequently commented on spontaneously by subjects experiencing trance for the first time. Such distortions are also characteristic of patients with organic disturbances of the right hemisphere. Luria reports several other patterns of right-hemispheric dysfunction that are similar to spontaneous phenomena of trance. Patients with deep lesions of the right hemisphere showed severe loss of spatial orientation and disturbances of the time sense. As we have seen in this volume, time distortion is highly characteristic of trance, and one of the most reliable signs of people awakening from trance are their efforts to reorient to their own bodies. Luria even reports "trance logic" in such patients wherein they firmly believe they can be in two places at once, just as do some hypnotic subjects when they are experiencing visual hallucinations (Orne, 1959).

These correspondences indicate that in the typical trance right-hemispheric functions can be depressed just as well as those of the left. In fact, because of the more global and diffuse character of right-hemispheric functioning, the right hemisphere may be more easily altered than the left. Because of this we frequently witness the disturbances of body schema, etc. without any blocking of the more focal linguistic-logical functions of the left. This is particularly characteristic of highly intellectualized subjects (Barber, 1975), who may accurately describe the sensory-perceptual distortions their right hemisphere is experiencing with the unimpaired verbal logic of the left hemisphere. Luria also comments on this situation, where patients will make an effort to mask changes in personality and consciousness due to lesions of the right hemisphere with glib verbal formulations. This sounds very similar to the mode of highly intellectualized subjects, who tend to deny that trance or an altered state was experienced. Such subjects are probably both right and wrong. They are right in denying any alteration in their left-hemispheric functioning but are wrong in denying and remaining unaware of alterations in their right-hemispheric functioning. This very denial of any disturbance in functioning is also characteristic of patients with organic dysfunctions of the right hemisphere.

These considerations indicate that it may be too simple to view trance as a function of the right hemisphere. The way trance is usually induced with suggestions for relaxation and comfort tends to alter the functioning of both left and right hemispheres. We can understand why right-hemispheric functions are usually more obviously altered than those of the left, however. Since the left hemisphere is dominant and more focal in its functioning, the right hemisphere tends to be depotentiated more easily in the early stages of learning to experience trance. Most people have well-established habits to maintain and control their left-hemispheric functions more than those of their right, so the right hemisphere tends to be more easily depontentiated or altered than the left. And since the left hemisphere is the center of verbal-logical consciousness, it can contradict or "defend" itself against the verbal-logical suggestions of the hypnotherapist. The right hemisphere, by contrast, is used to cooperating with the verbal-logical formulations of its own left hemisphere. The right hemisphere thus need only generalize this function of cooperation to go along with the verbal suggestions of the therapist.

These recent studies of the characteristics of left- and right-hemispheric functioning can thus greatly enhance our understanding of trance phenomena. They provide a source of interesting hypotheses for further explorations of trance experience and suggest means for refining classical procedures as well as the invention of new methods. This neuropsychological approach takes the verbal "magic" out of suggestions and provides us with a sound rationale for understanding hypnotic susceptibility as a function of both genetic and learned patterns of individual differences in behavioral response.

EIGHT

Infinite Patterns of Learning: A Two-Year Followup

After one final session, during which Dr. S discussed her initial efforts and problems in beginning to use hypnosis in clinical practice, Dr. S felt she had sufficient work with Erickson for the present and planned to continue her training in the workshops of the American Society of Clinical Hypnosis and under professional supervision where she worked.

Two years later she was contacted for a followup. She reported that in the intervening period she had continued her training in hypnotherapy and was using it regularly in her clinical practice. When she came for the actual interview, she sat in the same chair where she had experienced her hypnotherapeutic training with Erickson. As she sat down and adjusted herself, it was immediately obvious that she was taking her habitual posture for induction, with her hands on her thighs, etc. Erickson recognized this body language and without a word simply looked at her as he usually does when inducing hypnosis. By reproducing the hypnotic situation in this way, Dr. S immediately went into a very deep trance, deeper than any she had experienced previously.

The followup interview thus became another step, a very profound one, in Dr. S's training. Erickson uses one of his own dream experiences to initiate a "two-stage dissociative regression" wherein Dr. S experiences a genuine state of hyperamnesia and recovers memories from a phase of her childhood that she had entirely forgotten. Erickson then initiates a series of open-ended suggestions that would set Dr. S on an infinite path of inner experiential learning. He successfully draws a curtain of amnesia over these suggestions so that Dr. S's conscious mind cannot interfere with them. But the new experiential learning would be available whenever Dr. S needed it.

Dr. S did manage to recall a bit of what her very deep experience was like in this session before Erickson initiated the process of amnesia. She wrote a few revealing paragraphs, "Reflections After Trance Induction," to describe her experience.

Of particular interest in this session is Erickson's illustration of the type of open-ended suggestions that can give rise to infinite patterns of learning that can be of life-saving value. He discusses the Pearson incident, where open-ended suggestions given to a student were utilized by him years later in an emergency situation, where he was able to self-induce anesthesia and an accelerated healing of the physical body after being hit on the head with a brick.

The infinite possibilities of learning initiated by trance work were also illustrated by Dr. S's ingenuous response to reading these transcripts two years after they occurred. She reported that in these two years she had thought of herself as particularly inventive in her approaches to initiating her patients into trance and the therapeutic uses she developed for trance in groups as well as individuals. Upon reading these transcripts, however, she realized how many of her "original" approaches had their origin in one thing or another that Erickson had said or done here or there. Her trance experiences with Erickson had obviously interacted with her own creative processes to originate new thinking and behavior patterns.

Body Language and Expectation of Trance

After being introduced to Dr. Z, who was present as an observer, the interview proceeds as follows. S sits comfortably with her palms on her thighs, exactly as she did two years ago when she was ready to enter trance. Erickson instantly recognizes this readiness and without saying a word begins to look steadily and expectantly into S's eyes.

S: You are staring at me again.

E: Describe your feelings as you sit there.

S: Oh, I feel fine. Relaxed and comfortable.

[Pause as E and S continue to look into each other's eyes. S then blinks slowly a few times.]

E: Now I thought that was very interesting the way she sat down and began to sink back into two years ago. All I did was give a look of confident expectation. Now that's the important thing. An infant learning to walk, you know he can learn to walk, but the infant doesn't know. You give the infant the confident support of your expectation.

R: Her body language cued you into the fact that she was ready for trance work. Your expectant look silently acknowledged that readiness and permitted her to enter trance without a word being said.

Ocular and Visual Alterations During Trance Induction: Fogging Phenomenon and Trance Stare

S: It is getting foggy again.

(Pause)

Getting more

relaxed.

[Pause as the looking continued for a few moments longer until S finally closes her eyes, takes a deeper breath, and quite obviously enters trance with a relaxation of facial muscles and an absolute immobility of body.]

E: And now enjoy very much going deeper and deeper. (Pause)

R: She experiences this fogging even before she closes her eyes. It's her usual way of experiencing the first stages of trance, just as she did two years ago. She also demonstrates the "trance state" when she experiences this fogging. Her eyes have an unblinking stare, a fixity of regard or a faraway or distant look. Weitzenhoffer (1971) regards the trance stare as due to a decrease in the blink rate together with an appreciable decrease in the spontaneous, random, saccadic movements of the eyeball. Other subjects report all sorts of subjective changes in the visual field during trance induction: alterations in the color background, tunnel vision, perceptual distortions, illusions, blurring, an apparent decrease in illumination, a veil before the eyes, a grayness over the visual field, and similar changes.

Deepening Trance

It is often said,

we learn to skate in the summer

and to swim in the winter.

We achieve certain

level of learning

to skate in the winter.

But the next winter

we start skating with a higher degree of excellence.

Because the random movements of skating

that complicated the first learning

have dropped out.

And the first winter

the random movements

were still fresh in mind.

(Pause)

Now you can go

much deeper

because

there are many fewer

random movements

or processes.

R: This was a new way of deepening trance after a long period of absence from experiencing an induction. You simply describe a truism of the learning process: random movements drop out during a period of rest. Therefore, this will be an even deeper trance , than before.

E: And that is a past experience everyone has had.

R: So you've deepened trance by utilizing an innate learning process we all have experienced.

E: You learn to write by grimacing your face and moving your feet, but after a while these random and irrelevant movements drop out.

Open-Ended Suggestions

And now I don't know

what particular experiences

you want to sense.

I don't know if you have any conscious idea,

but always the unconscious mind has its own thoughts.

Its own desires.

(Pause)

And you can feel very pleased

in discovering

what your unconscious is going to do.

(Long pause)

And it will be your own experience.

(Pause)

And experience can be any place,

any time,

in any situation.

(Pause)

To look at one self

doing something

is always a charming thing.

(Pause)

I can give you a personal account.

In 1930,

in the early May,

I dreamed one night

that I was on the north side of an

east and west road.

in Wisconsin.

R: Here you begin a typical pattern of open-ended suggestions. You begin depotentiating consciousness by saying that you , "don't know," and that implies that it is okay if her conscious mind does not know either. But you emphasize that the unconscious does have thoughts and desires, and you reinforce them by noting that she can be pleases to discover what her unconscious is going to do. As her "reflections" later indicate, she did use these open-ended suggestions in a manner that was uniquely her own. You emphasize the open-ended aspect of your suggestion by mentioning that it will be *her experience* any time, any place, any situation. This sounds like a great deal of freedom. It is freedom as far as the conscious mind in concerned, but it is being highly determined by her own unconscious.

Two-State Dissociative Regression

And I stood there

knowing that I was Dr. Erickson.

And I was looking at a small boy

who was running up and down.

By the grading on the side of the road by the hills

was a maintenance crew.

A fence on the top of the grade

and barbed wire fence.

Hazel bush,

an oak tree,

a wild cherry tree.

And I saw that barefoot boy with overalls

curiously probing the freshly graded ground,

and excavating around the cut ends of the roots,

and looking at the oak tree,

and looking at the wild cherry tree,

and then examining the cut ends of the roots,

trying to determine

which roots came from the wild cherry tree

and which came from the oak tree.

The little boy was sure

none of those roots came from hazelnut bush.

I approved of that boy.

I could see him plainly.

I recognized him

as little Milton Erickson.

> R: This two-state dissociative regression wherein a person sees and sometimes even relates to himself at an earlier age level was well described in your trance work with Aldous Huxley (Erickson, 1965). You hoped to trip off this state in S by giving this charming example of how it occurred to you in a dream state, where it is not uncommon (Rossi, 1972, 1973a). As Dr. S remarks in her "reflections" on this session, you did succeed at this point because she did see herself as a child reading a book by Louisa May Alcott. She reports the actual recovery of memories from an entirely forgotten phase of her life when she wanted to be a writer. That is, she experienced a genuine *hypermnesia!*

Trance as an Atemporal Theater: Active Imagination and Psychosynthesis

But he could not see Dr. Erickson.

He didn't even know I was on the other side of that east-

west-bound road.

And I enjoyed watching that little boy. And thinking

but how little appreciation he had of the fact that he was going to grow up and become Dr. Erickson.

And then the dream terminated.

In September of that year

I did take a vacation trip to Wisconsin.

I went to the county seat,

got out all the records

of the county road maintenance work.

And I found out where that road was.

And then I drove to that area.

I found out how it was possible for

me to have been there.

There is a gravel pit near that road.

1 remember going there with my father when he got a load of gravel.

But I had no memory of ever examining that

fresh grading in the road.

But I found there was a hazelnut bush,

an oak tree,

and a wild cherry tree.

And I was still a little boy,

a barefoot boy.

I had long forgotten that,

but my unconscious mind

had remembered it.

(Pause)

> R. It is utterly fascinating how in dreams and trance states the personality can encounter itself at different age levels as if time did not exist. This was particularly clear in your work with Huxley. These are states of active and creative imagination wherein the person as an adult personality can actually relate to and help himself as a child. In this way old traumas and needs, just about any form of "unfinished business," can be resolved. This is a form of psychological healing that I believe is the essence of any form of therapy, whether it takes place in dreams, trance, free association, active imagination, meditation, or whatever. The common denominator is that something new is synthesized within the personality (Rossi, 1973b).

Reading Minimal Body Movements in Trance: Eye Movements in Trance

I'm suggesting this to you as a possible experience.

(Long pause)

I began work on the research service

in Worcester, Mass.

and was tremendously interested

in the thinking and behavior of people

at various levels.

And I knew I was going to Wisconsin on vacation in September.

And so my unconscious mind

furnished me with an opportunity

of observing myself

at a previous age.

(Pause)

And you work with patients

and you work with your understanding

and your understandings come

from your knowledge

of how you behave.

In your observations

of the behavior of others

(Pause)

you need

to have a vivid observation

of your own past behavior

(Long pause)

E: Now it is my interpretation that she was a bit abashed by Dr. Z's presence. But I think Dr. Z isn't here now [for Dr. S]. As far as I can judge, there are quite a number of mobile memories being manifested.

R: How can you tell?

E: By those muscle quiverings around that elbow. And the alterations of her breathing are very suggestive of mobility. Sometimes those are suggestive of, for example, going for a walk in the woods.

R: What is the meaning of those slight vibratory movements of the eyes?

E: Sometimes they are random movement, sometimes they signify a kind of relaxation. You don't know really. I think a proper thing to do is let her discover bit by bit more and more things about herself.

R: You like to have your patients discover and tell you about these minimal movements rather than making spurious generalizations about them. This is very wise because individual differences between people are so great in trance experience it is really difficult to relate inner events to external behavior in any consistent way.

E: That's right.

R: Weitzenhoffer (1971) has investigated "slow eye movements of a pendular (sinusoid) type resembling those which have been reported to accompany Stage I of natural sleep and certain other altered states of consciousness. ... At such times the subjects have been found to be still responsive to the hypnotist." Spiegel (1972) has found eye-roll (the ability to look upward on signal while closing the eyelids) and squint during induction to be indications of clinical hypnotizability. Other investigators (Switras, 1974; Wheeler et al., 1974), however, have found no relation between eye-roll and other measures of hypnotic susceptibility in the laboratory. Ancient images as well as modern photographs of yogi in meditation also show the upward roll of the eyeball. Even though there are great individual differences in eye behavior during trance, it can be studied for whatever clues it provides regarding altered states of consciousness.

Amnesia:
Protecting Trance Learning from Consciousness

Now it isn't important

for you

to recall

what you have achieved

here today.

Your unconscious can unfold it to you ,

in bits and parts

at the appropriate time,

and you will have a good understanding.

And anything not remembered today

is still recorded in your mind. (Pause)

R: In her later "reflections" Dr. S reported that this remark did in fact cause a dramatic and unwanted amnesia.

E: I'm giving Dr. S an opportunity for inner experiential learning in this trance, which she won't know about until the time is right to use it.

R: You don't want her to know about it till the time is right because you don't want her conscious mind to interfere with it.

E: I don't want her conscious programs to depotentiate it!

R: So theoretically a patient could leave feeling you've done absolutely nothing for her?

E: That's right! And they often do!

R: Until later, when they call you up with reports of the value of what you've helped them accomplish.

E: That's right.

Facilitating Potentialities:
Not Knowing and Open-Ended Suggestions for Infinite Learning:
Anesthesia and Body Healing

You need not know today

that perhaps you are anesthetized completely.

That you are immobilized completely.

(Pause)

You need not even know

if you have

dissociated yourself from your body.

At the right time you will discover

All the things that you have accomplished.

you will repeat these learnings

subsequently.

And you are beginning to realize

that you are a far better subject than you previously thought.

(Long pause)

And you keep right on in a trance,

learning the things you need to learn.

And I'm going to turn away from you and talk to Dr. R.

[Long pause during which Erickson quietly talks to Drs. Z and Rossi.]

E: In therapy this is often the way you get patients to become aware of their capabilities. You are essentially giving them the freedom to use themselves. Patients come to you because they don't feel free to use themselves.

R. Now is this the way you gave Dr. Robert Pearson open-ended suggestions for the anesthesia that he was suddenly able to use in an emergency (Pearson, 1966)? You say you had never given him specific suggestions to experience anesthesia.

E: No.

R: But he was able to develop an anesthesia that may well have saved his life because years before you had given him such open-ended suggestions for the possibility of anesthesia when he might need it.

E: I told him, "You know a lot of things you need to know, only you don't know you know them. When the appropriate situation develops, use the appropriate learning."

R: Even though he had never experienced hypnotic anesthesia before, in an appropriate situation, in the emergency situation when a brick hit him on the head, he was able to develop a hypnotic anesthesia.

E: At that moment he said to himself, "If only Erickson were here." Erickson connoted hypnosis for him, and that meant he should use hypnosis.

R: He should use hypnosis for his obvious need in that emergency situation. So this is an extremely valuable suggestion you are giving to patients. You are stimulating in them an infinite number of learnings that they will be able to apply at the appropriate time.

E: That Pearson incident was a beautiful example of that. His associations to me were primarily about hypnosis, anesthesia, and the utilization of the unconscious. He added healing to that, better healing.

R: So he was able to effect faster body healing through hypnotic suggestion?

E: He was back lecturing in a few days with only a bandaid. His skull had been fractured and chips of bone taken out. The surgeon had expected him to pad around in his slippers for a few weeks.

Criteria for Trance Termination

[Erickson now studies Dr. S very intently for a few minutes.)

E: I don't know how to understand your finger movements,

the elbow movement,

the alteration in your breathing.

But comfortable,

slowly, agreeably,

bring your trance to an end

at a time of your own choice.

And come out of it feeling rested

and comfortable

and at ease,

with a sense of having done something very well.

R: What are you studying now?

E: I'm trying to determine how quickly I should awaken her.

R: What criteria are you using?

E: I don't know. I do know I won't do it now while she is taking a deep breath.

R: Why?

E: I don't know what is going on then. If you awaken a subject at the wrong moment, they resent it. They can then demand that you put them back in trance so they can finish.

R: How do you know when they are finished and ready to awaken?

E: You look for a quiet moment when all you can see is comfort.

Amnesia by Distraction

[Pause as Or. S reorients to her body, opens her eyes, and awakens. As soon as she opens her eyes, before she is completely awakened, Erickson quickly distracts her.]

E: Did Dr. R ever tell you about my ironwood carvings?

S: Wha...?

E: Did Dr. R tell you about my ironwood carvings?

S; Ironwood carvings?

E: And yesterday I became the proud possessor of a frog riding a tricycle.

S: [laughs] Just what everybody needs, I guess.

[With laughter and mirth all around Erickson continues to talk about everything under the sun except anything related to the session that has just taken place. We all then join him to look at the ironwood carvings in the living room of his home.]

E: Now what I had to do was awaken her and distract her so whatever she has done can remain at the unconscious level. I don't want it shoved into a conscious frame of reference.

R: You produced an hypnotic amnesia by distraction (Erickson and Rossi, 1974), and by this means you hoped to keep the trance work effective at an unconscious level. As her later "Reflections" indicate, you were highly effective in facilitating this amnesia even though she greatly regretted it. Some material did slip through to consciousness, and this is the essence of her reflections.

REFLECTIONS AFTER TRANCE INDUCTION

by Dr. S

I first experienced fog and then trance, relaxed.

In response to Erickson's comments (roots, etc.) I remember various childhood memories including a forgotten phase where I wanted to be a writer—I see myself reading a book by Louisa May Alcott at the beach and planting a maple tree from seed which grew outside my bedroom window.

Scenes of walking on the beach, etc.

I think I must tell Dr. Erickson my wart is gone [Dr. S removed a wart on her own finger by self-hypnosis] and that I have gotten to be a smoother therapist. Patients comment, "She helps you and it doesn't hurt." I feel somewhat pleased.

I remember feeling my body numb and still.

I hear Dr. Erickson say something like "You won't have to remember what happens." Then, suddenly, I look and my memories become fogged up. Then I see myself in a bed reflecting to myself," You are really going into a deep sleep— you will be so relaxed you won't remember your dream."

I can't remember anything after that. But have a feeling I was in a dream-phantasy trance for some time. I wake up after a suggestion (that's the first thing I can recall) relaxed, serene, satisfied and great!

Apart from her interesting comments on fogging, the recovered memories from a forgotten identity phase of childhood (wanting to be a writer, the numbness of her body, and her apparent psychosomatic healing in removing a wart through self-hypnosis, Dr. S's description of how she experiences her amnesia is particularly revealing. She reports that Erickson's words are transformed in her mind into a visual image of herself in bed "really going into a deep sleep—you will be so relaxed you won't remember your dream."

Erickson maintains that all successful suggestion contains this process of transformation whereby the therapist's words are reformulated in a manner that is consistent with the personal psychodynamics of the subject. Thus it is very important to facilitate this transformation process with permissive suggestions that are formulated in as open-ended a manner as possible. Erickson frequently reinforces this tendency by directly suggesting that the patient's unconscious can hear and transform the therapist's words in any way that would be most suitable for its own functioning.

INFINITE POSSIBILITIES OF CREATIVITY, HEALING, AND LEARNING

The depotentiation of a subject's limited and habitual frames of reference together with open-ended suggestions to facilitate new possibilities of creativity, healing, and learning appears to be one of the most exciting prospects opened by Erickson for a hypnotherapy of the future. His life work has demonstrated the possibilities of utilizing trance as an inner-directed experience wherein one can get free from some of the learned limitations of previous history and training. The mind is an incredibly vast reservoir whose potentials are still unrealized by most people. Trance is a free period for the inner discovery, exploration, and realization of these potentials. At the present time we see only the tip of the iceberg of the possibilities of human nature. Hypnosis has been greatly hampered by its past image of being a technique for manipulation and control. How boring to deal with manipulation and control when we can be facilitating new possibilities of human nature undreamed of by either therapist or patient. Like dream, reverie, and creative states of imagination, trance can be a period for free development. The art of the modern hypnotherapist is in opening up the possibility of this development by helping each individual outgrow his own learned limitations.

NINE

Summary

Our approach in this volume has been to make a detailed analysis of the actual words and approaches of one outstanding clinician in the area of hypnotherapy. Our object has been to learn as much as possible about Erickson's approaches so that other clinicians and research workers could study, test, and utilize our findings. Because Erickson's approaches presuppose a certain amount of clinical skill, a major goal of this volume has been to carefully delineate exactly how Erickson goes about his work, the observations and inferences he makes, and the hypotheses he tests. Any fair evaluation of his approaches requires that the clinician and researcher acquire some of Erickson's hypnotherapeutic skills. To facilitate this process of skill acquisition, we have outlined the types of study and exercises that other workers might well pursue to further their clinical practice and research in hypnosis.

To help the reader organize the material of this volume we will summarize some of its basic ideas under four major headings:

1. The Nature of Therapeutic Trance
2. Clinical Approaches to Hypnotic Induction
3. The Forms of Hypnotic Suggestion
4. The Facilitation of Human Potentials

I. THE NATURE OF THERAPEUTIC TRANCE

Erickson tends to be atheoretical and pragmatic in his approach. His knowledge comes from practical experience about what works rather than theoretical speculation. He has never formulated an overall theory of hypnosis, and it is only with some prompting that he will express himself on theoretical issues. The following views about therapeutic trance are definitely expressed throughout this volume, however.

a. Trance Viewed as Inner Directed States

Trance phenomena may be understood in the broadest sense as inner-directed states wherein the multiple foci of attention so characteristic of our usual everyday consciousness are restricted to relatively few inner realities. Because of this restricted focus, new learning can proceed more sensitively and intensely in trance when the patient is not interrupted by irrelevant stimuli and the limitations of his usual frames of reference.

b. Trance Viewed as a Highly Motivated State

Erickson carefully notes and utilizes a patient's personal psychodynamics and motivation for initiating and developing trance experience. It is patients' motivation that will bind them to their task of inner focus. It is this uniquely personal motivation that may account for some of the differences found between laboratory hypnosis (where standardized methods are used that tend to exclude the subject's individuality) and clinical hypnosis (where the patient's individuality is of essence in the approaches used for trance induction and utilization).

c. Trance Viewed as Active Unconscious Learning

Fundamental to Erickson's approach is his view that patients have problems because of their learned limitations. The object of trance is to relax these learned limitations of the patient's usual frames of reference to permit the vast reservoir of their unrecognized potentialities to operate. Freed from the common sets, biases, and inhibitions of consciousness, learning can proceed on an autonomous or what is conventionally called an unconscious level. In the ideal case Erickson first clears the mental stage from the clutter of a patient's learned limitations and then helps patients utilize their own unique life experience and associations to create and restructure themselves from within on an unconscious level without the mediation of consciously directed thinking. Trance is thus an *active process of unconscious learning* somewhat akin to the process of latent learning or learning without awareness described in experimental psychology (Deese and Hulse, 1967). This is different, indeed, from the crude conception of hypnosis as a passive and regressed state where the patient is an automaton under the control of the operator.

d. Trance Viewed as an Altered State of Functioning

The research literature of the past decade has dealt extensively with the contrasting views of trance as an altered state versus the view of trance as simply a motivated situation wherein the subject follows the operator's instructions as well as possible. The difficulty in resolving this controversy is in a definition of what constitutes an "altered state" and the development of objective measures of the "altered state." In a recent paper on hypnotic amnesia (Erickson and Rossi, 1974) the authors have made a case for the "state theory" of clinical hypnosis as follows.

Researchers (Fisher, 1971) have recently investigated *state-dependent learning* in a number of ways. One group of subjects memorize nonsense syllables while drunk. It is then found that they are better able to recall them on a later occasion when they are drunk than when they are sober. Recall is thus state-dependent; recall takes place better when people are in the same state they were in when exposed to the learning. Other investigators verified the same state-dependent phenomenon with amphetamine-induced excitatory states and amobarbitual-induced inhibitory states. Fisher generalizes these results into a theory of "how multiple existence became possible by living from waking state to another waking state; from one dream to the next; from LSD to LSD; from one creative, artistic, religious or psychotic inspiration or possession to another; from trance to trance; and from reverie to reverie."

We would submit that therapeutic trance itself can be most usefully conceptualized as but one vivid example of *the fundamental nature of all phenomenological experience as "state-bound."* The apparent continuity of consciousness that exists in everyday normal awareness is in fact a precarious illusion that is only made possible by the associative connections that exist between related bits of conversation, task orientation, and so on. We have all experienced the instant amnesias that occur when we go too far on some tangent so we "lose the thread of thought" or "forget just what we were going to do." Without the bridging associative connections, consciousness would break down into a series of discrete states with as little contiguity as is apparent in our dream life.

It is now a question of definition and of further empirical work to determine whether these states are discrete and different in mental content alone or whether more gross physiological indicators can be used in defining them. A drug obviously introduces a physiological change that may or may not be measurable with current techniques. With therapeutic trance the case is more equivocal. The case is further complicated by the fact, as Fisher indicates above, that once an altered state is produced, "symbolic" associations alone are sufficient to reinduce it.

How can we reconcile this special-state theory of hypnotic trance with the many informative experimental studies that support the alternative paradigm (Barber, 1969) of hypnosis as a "responsive waking state" that is not discontinuous or essentially different from

normal ordinary consciousness? In many of his papers Erickson (1939, 1952, 1966a) has emphasized that deep or really satisfactory trance experience depends on the ability to subordinate and eliminate waking patterns of behavior; that is, to give up some of the learned limitations and habitual frameworks of one's characteristic conscious attitudes. To achieve this end Erickson evolved many new techniques of induction and stressed the need for careful "hypnotic training" whereby the individuality of each subject was carefully taken into account to maximize the presence of involuntary or autonomous behavior in trance with as little participation of habitual conscious attitudes and mental frameworks as possible. In his early work Erickson rarely gave therapeutic suggestions until the trance had developed for at least 20 minutes—and this only after hours of previous hypnotic training. After years of experience his clinical evaluation of the patient's psychodynamics and current mental state enabled him to work much more rapidly.

In actual practice it is admittedly difficult if not impossible to eliminate all waking patterns. This is particularly true in the typical experimental study, where standardized instructions and direct suggestions are utilized with little or no extensive hypnotic training directed to the elimination or at least the mitigation of habitual conscious patterns in trance. The presence of many verbal, sensory, perceptual, and psychodynamic associations common to both the trance and waking situation in most experimental studies bridges the gap between them and further reduces their discontinuity. We would therefore submit that the alternative paradigm, which views the trance and waking conditions as more or less continuous, with no evidence of a "special state of trance," is correct in evaluating the typical experimental situation. It does not, however, adequately conceptualize those clinical situations where the skill of the therapist together with the needs of the patient interact to produce the striking discontinuities between trance and the normal state of consciousness that are so suggestive of special-state theory.

This issue is analogous to the heated controversy about the fundamental nature of light as continuous (waves) or discontinuous (particles) that plagued physicists during the first quarter of this century. In practice it has been found helpful to think of light sometimes as waves and other times as particles. The most adequate conceptualization, however, is through mathematical symbols that cannot be meaningfully related to in terms of everyday associations on the verbal and imagery level. Likewise in clinical practice it may be most helpful to conceptualize and stress those antecedent and mediating variables that promote discontinuity between trance and waking state, while in experimental work there may be more theoretical interest in dealing with the continuities.

e. The Subjective Experience of Trance

The subjective experience of trance naturally varies as a function of an individual's personality and life history (Hilgard, 1970) as well as of the approach used for trance induction and utilization. One common denominator in the experience of most of Erickson's patients is that in trance things seem to happen by themselves. As was so well demonstrated with the experiential learning of trance phenomena by Dr. S, there is a sense of surprise when a hand levitates or an ideosensory phenomenon is manifest.

The contrast between what happens by itself and what we seem to control and direct is in fact one of the most profoundly interesting things about the subjective experience of mind. Our mental life is a dialogue between what happens to us and what we do about it. Sensations, perceptions, emotions, moods, dreams, fantasies and associations are always happening spontaneously on an unconscious level and presenting themselves to the threshold of consciousness. How we learn to respond to these spontaneous presentations determines in great part our sense of reality, mental health, and well-being. We can respond, for example, to the new that occurs to us in perceptions or in dreams with, on the one hand, fright, flight, and phobia or with curiosity and creativity on the other hand (Rossi, 1972a).

From our earlier statement of trance as a process of unconscious learning it would follow that trance deals primarily with those autonomous processes that make presentations to

consciousness. But things are not that simple. In most experiences of trance some observer ego is present, quietly taking in the scene; the patient is quietly watching what is happening within (Gill and Brenman, 1959). It is this observing ego that gives a detached, impersonal and objective quality to much of the conscious ideation in trance. The objective quality of this ideation makes it particularly useful in psychotherapy. As long as this observer ego is present, however, many patients will insist they are not hypnotized; they equate the observer function with being conscious in the normal sense of the word.

Erickson is always concerned about this observer function, and many of his approaches are designed to jostle it about and depotentiate it. Not that consciousness itself is a problem in trance, but rather its associated functions of directing and controlling are the problem. In trance the ego alters its habitual patterns of control and direction, while varying degrees of the observer function remains intact. This permits two things to happen:

1. The autonomous (unconscious) presentations (everything from sensations and emotions to dreams and spontaneous associations) are freed to function spontaneously without the restrictions of the ego's usual frames of reference.
2. The interface between these autonomous presentations and the observing ego can be broadened so that, in effect, more of the unconscious can become conscious.

Erickson's preference is for therapy to proceed by the first process alone. He is always delighted when the patient solves his problem without knowing how he did it.

The more conventional forms of depth psychotherapy proceed by the second process of making more of the unconscious conscious. Erickson has used this process as one step in some of his overall plans of hypnotherapy (Erickson, 1954, 1955).

2. CLINICAL APPROACHES TO HYPNOTIC INDUCTION

a. Orientation to Hypnotic Induction

The purpose of trance induction is threefold.

1. to reduce the foci of attention (usually to a few inner realities).
2. to facilitate alterations in the subject's habitual patterns of direction and control.
3. to facilitate patients' receptivity to their own inner associations and mental skills that can be integrated into therapeutic responses.

Ordinarily this is very simply accomplished by Erickson when he tells a patient to sit in a certain way, focus on a spot, and remain quiet while Erickson talks. Erickson then embarks on a train of associations that will help the patient focus attention inward on memories, feelings, and all sorts of associations, developmental patterns, and learning experiences. In this Erickson is not so much suggesting (in the sense of putting something into the patient's mind) as he is evoking. The effectiveness of his words is in their calculated design to evoke preexisting patterns of association and natural mental processes in the patient. He can evoke memories because the memories are already there in the person. He can evoke amnesia, anesthesia, or any other hypnotic phenomenon only because there are built in mechanisms for these processes already existing in the patient.

Erickson watches patients very carefully during induction. Induction is certainly not a standardized and mechanical procedure where he parrots some formula by rote. Erickson carefully notes where patients are all the time. The precise moment he chooses to begin an induction might be when he senses that patients need to focus inward and alter some limiting aspect of their conscious attitude and belief system so that therapy can proceed. Erickson understands trance as a normal experience of everyday life that occurs naturally whenever a person becomes deeply absorbed in some inner or outer reality (e.g., daydreaming or

listening to music). Erickson notes the beginning signs of trance and then simply reinforces them in any way that is particularly appropriate for a particular person in the here and now circumstances.

Erickson has commented that he can recognize potentially good subjects in an audience by noting those who seem "frozen" (relatively little body movement) and those who exhibit "response attentiveness" (those who become very absorbed in what another is saying or doing). The moment when these characteristics are manifest in the therapy session is obviously the best time for trance induction. If they do not become manifest naturally, Erickson might initiate them by focusing and fixating the patient's attention with an interesting story, anecdote, or whatever is motivating and absorbing for that particular patient. These interesting stories may seem irrelevant to the casual observer, but through them Erickson is actually initiating a "yes set" and following behavior by the patient that will gradually lead into the induction phase proper.

Erickson has described the state of response attentiveness as the common "everyday trance," and he frequently utilizes this natural form of absorption just as he would trance. Even without any form of formal trance induction, patients will become so absorbed in what he is saying that they later wonder if Erickson had somehow, without their knowledge, put them in trance. "Suggestions" made while the patient is in this state of absorption can be just as effective as when in formal trance. Trance thus need not be formally induced for effective clinical work. The approaches to clinical induction described in this volume are simply a convenient means by which the therapist can initiate a process of inner focus and unconscious learning.

b. Approaches to Hypnotic Induction

It is well that we speak of "approaches" to hypnotic induction rather than "methods" or "techniques." These latter words have connotations of being mechanical, hard-and-fast procedures that one imposes on a person. Erickson imposes nothing. He simply tries to evoke the natural process within patients that will enable them to be receptive to their own inner realities and experience the possibility of new creative inner work being done to resolve a problem.

Erickson has developed a bewildering variety of "approaches" to these ends. As was illustrated in this volume he will frequently use a variety of these approaches in the same session. With each approach he learns something new about the patient's characteristic ways of responding. He accepts whatever response the patient makes as adequate. How could it be other than adequate since it is an expression of the patient's individuality? It is in this individuality that a unique solution will be found for his unique problem. These responses teach Erickson something about the patient's individual ways of responding (the patient's "behavior hierarchy"), and he uses this knowledge as a kind of feedback that allows him to modify his approaches to further fit the individuality of patients to help them achieve the inner direction and receptiveness that are so characteristic of trance.

We can in summary list some of the particular and general approaches to trance induction that are illustrated in this volume. All of these approaches can be used for either direct or indirect induction of trance, depending on how they are presented to the patient.

Particular Approaches	*General Approaches*
Early learning set	Conversational
Eye fixation	Confusion
Hand levitation	Pantomime
Handshake induction	Conditioning
Mutual trance induction	Experiential
Posthypnotic cue	Introspection-imagination
Evoking previous trance associations	Surprise
Rhythm induction	Question

Shift in frames of reference
Heightened-awareness

Most of these approaches can be described as more or less indirect because consciousness is not entirely aware of exactly what is happening. Consciousness understands something of what is happening but not all. Things soon seem to begin happening all by themselves, conscious sets are further depotentiated, and trance begins. We have described the microdynamics of trance induction and suggestion with a number of flow diagrams that could be summarized as follows:

Fixation of attention	via	The amazing, unusual, standard approaches to hypnotic induction or anything that attracts and holds the subject's attention.
Depotentiating conscious sets	via	Shock, surprise, distraction, dissociation, and other hypnotic forms.
Unconscious search	via	Implication, questions, analogy, and other indirect hypnotic forms.
Unconscious processes	via	Summation of literal and personal associations and mental mechanisms structured by all the above.
Hypnotic response	via	Expression of behavioral potentials experienced as taking place all by themselves.

c. Depotentiating Habitual Frames of Reference

When we state that the purpose of clinical induction is to focus patients inward and help them alter the controlling and directing functions of their habitual attitudes and belief system, we are in effect helping them depotentiate their usual everyday consciousness. Because of the limitations of their habitual frames of reference, their usual everyday consciousness cannot cope with certain inner and/or outer realities, and they recognize he has a "problem." Depotentiating patients' usual everyday consciousness is thus a way of depotentiating their personal limitations. Depotentiating the limitations of an individual's usual patterns of awareness thus opens up the possibility that new combinations of associations and mental skills may be evolved for creative problem solving within that individual.

So subtle and pervasive are Erickson's approaches to depotentiating conscious sets that they have taken a significant place in most of our commentaries. They have also been listed as a major topic in most of our essays concerned with the description and dynamics of Erickson's hypnotic forms. Here we can only list some of the hypnotic forms that can be utilized to depotentiate a subject's habitual frame of reference.

Absence of challenge

Casual and permissive manner

Amnesias structured continually

Boredom

Confusion

Continually redirecting attention

Contradictions

Dissociation

Double bind

Doubt

Expectancy and need for closure

Involuntary signaling

Losing abilities

Negations

Displacing doubt and discharging resistance

Partial remarks and dangling phrases

Questions that distract

Rest

Tasks outside patient's usual frames of reference

Using therapist's rhythm

Voice locus and emphasis

Yes set

You don't need to know

d. Indicators of Trance Development

Once induction has begun, Erickson recognizes a variety of indications of developing and deepening trance such as the following. Trance experience is highly individualized, however, and patients will manifest these indicators in varying combinations as well as in different degrees.

Autonomous ideation

Balanced tonicity (catalepsy)

Changed voice quality

Comfort, relaxation

Economy of movement

Eye changes and closure

Facial features ironed out

Feeling distant

Feeling good after trance

Lack of body movement

Lack of startle response

Literalism

Retardation of reflexes

- swallowing
- blinking

Objective and impersonal ideation

Pupillary changes

Response attentiveness

Sensory, muscular, and body changes

Slowing and loss of blink reflex

Slowing pulse

Slowing respiration

Spontaneous hypnotic phenomena

- Amnesia
- Regression
- Anesthesia
- Catalepsy
- Time distortion
- etc.

Time lag in motor and conceptual behavior

As these indications become manifest (usually over a period of 10 to 20 minutes), Erickson gradually introduces verbalizations designed to evoke recognizable responses from patients to indicate that they are in rapport and are following Erickson. These can vary from head nodding or shaking to hand levitation and, bit by bit, other hypnotic phenomena that are

useful for training that particular patient in trance work so he can eventually accomplish his therapeutic goals.

It is of interest to note that Erickson looks for the spontaneous development of such hypnotic phenomena as age regression, anesthesia and catalepsy as more genuine indicators of trance than when these same phenomena are "suggested." When they are directly suggested, we run into the difficulties imposed by the patient's conscious attitudes and sets. When they come about spontaneously, they are the natural result of the dissociation or the loosening of ego control over the general reality orientation that is characteristic of trance.

Certain investigators have selected some of these spontaneous phenomena as defining characteristics of the fundamental nature of trance. Shor (1959) and Meares (1957), for example, have taken regression as a fundamental aspect of trance. From our point of view, however, regression per se is not a fundamental characteristic of trance, although it is often present as an epiphenomenon of the early stage of trance development, when the patient is learning to give up ego control. In this first stage of giving up ego control many uncontrolled things happen, including spontaneous age regression, paresthesias, anesthesias, illusions of body distortion, psycho-somatic responses, time distortion, and others. Once patients have learned to stabilize these unwanted side reactions, they can then allow their unconscious to function freely in interacting with the therapist's suggestions without the mediation of their conscious ego.

e. Ratifying Trance

Since the observer function of the ego is usually more or less present in trance, the patient will sometimes refuse to believe he was in trance, and this belief can limit further work. Because of this it is necessary to demonstrate that trance is in fact different from the ordinary awake state! Erickson describes this as "ratifying the trance." The most convincing ratification of trance is the therapist's astuteness in recognizing and pointing out the spontaneous hypnotic phenomena that are becoming manifest so the patient can recognize that he is involved in an altered or unusual state. All of the above-mentioned general indications of trance development are well suited for this purpose as well as any individual patterns a particular patient may manifest. In addition Erickson utilizes the spontaneous body reorientation on awakening as well as alterations in pulse and respiration as evidence of trance. In his experiential approach to trance he will have patients explore all the differences in their sensory, motor, and conceptual behavior between the trance and awake state.

Erickson frequently asks questions that involve a double bind to ratify trance. Any answer that is given to the question, "You really think you are awake, don't you?" tends to ratify trance by implication. Another such double bind question is, "Do you know if you were in a trance?" This question appears to ask for simple information, but either a "yes" or "no" answer ratifies trance ("yes" means trance with awareness; "no" implies trance without awareness). He regularly asks new patients what time it is as soon as they emerge from trance to ratify their trance by the spontaneous time distortion that is usually involved. Questions are always a particularly useful approach to ratifying trance because they elicit behavioral evidence from the patient's personal experience. This is vastly more convincing than any therapist's authoritative statements about the patient's state.

In awakening a new subject from trance by counting backward from 20 to one, Erickson will sometimes use the surprised reversal technique whereby he suddenly reverses the count (20, 19, 18 ... 12, 11, 10, 11, 12, 13 ... 20) so the subjects experience a "jerk" or mild vertigo as they suddenly feel themselves going back into trance as the numbers shift from backwards (awakening) to forward (deepening).

Erickson maintains that formal ritualistic techniques are not needed to induce trance. Any conversation that is really absorbing can entrance people without them necessarily recognizing their own trance state. In such cases Erickson believes they are listening and

capable of thinking and responding on the conscious and unconscious levels simultaneously. How does one ratify the fact that a trance is being experienced when a person evidences a high degree of response attentiveness? Simple! Erickson just asks for an autonomous response from the unconscious with a question such as, "If you have been in trance, your unconscious will let your right hand lift." Or, "If your unconscious thinks you've been in a trance, your eyelids will grow heavy and close." Obviously, not all investigators will agree with Erickson's approach and with his interpretation that affirmative autonomous responses to such questions are valid indicators that a trance existed. The subjects could be responding in a way that they believe Erickson wants them to. More clinical experience and controlled laboratory studies will be needed to settle such issues.

As we have repeatedly witnessed in the demonstrations of this volume, Erickson will use a buckshot approach in evoking many possibilities of posthypnotic suggestion. When any posthypnotic suggestion is then carried out, of course, it ratifies trance in a most convincing way. Probably Erickson's favorite approach to ratifying trance is to induce an arm catalepsy and then awaken the subject with the arm still cataleptic. The peculiarity of observing one's arm in an awkward position ratifies trance in a particularly vivid way. Throughout this volume the reader will note how carefully Erickson develops, supports, and then ratifies all of his suggestions as each hypnotic phenomenon becomes manifest. Trance and hypnotic phenomena are delicate, ephemeral, and evanescent in their appearance, particularly in the first stages of trance training. It is therefore necessary to strongly reinforce and ratify them when they do become manifest.

3. THE FORMS OF HYPNOTIC SUGGESTION

a. The Nature of Hypnotic Suggestion

Complex and multifaceted as they may seem, Erickson's approaches to suggestion have but one rationale: *suggestions are designed to bypass the patient's erroneously limited belief system; suggestions must circumvent the all too narrow limits of ordinary everyday consciousness*.

It has been estimated that most of us do not utilize more than 10 percent of our mental capacity. Erickson certainly believes this. Our consciousness usually has too narrow, rigid, and limited a conception of what it is capable of accomplishing. Ordinary education and daily life have taught us how to accomplish some things but have unwittingly biased us against many if not most of our capacities.

We all know from everyday experience that we can be so absorbed in something that interests us that we ignore everything else. We can "not hear" someone calling us and we can "not feel" pangs of hunger. Yet if you baldly ask someone to "not hear" or "not feel," they will look at you in disbelief. Our normal consciousness does not know how to "not hear" or "not feel" on direct command, even though the mental apparatus can do these things easily and automatically when the everyday conditions of ordinary life are suitable.

Erickson's indirect forms of suggestion are all means of arranging such suitable conditions so that individuals can accomplish things that are within their behavioral repertory but usually not available to voluntary control (although automatically and unconsciously available when the ordinary circumstances of life call for them, as illustrated above). The wonder and fascination of hypnosis is that it enables us to control these responses that are usually mediated by unconscious mechanisms outside the normal range of consciousness. The art and science of the hypnotherapist is in knowing enough about behavior and learning in general, and the individual experiences of each patient in particular, so the therapist can present suggestions to evoke all the responses necessary to accomplish a given therapeutic goal.

The theory is simple, but the practice is difficult until the therapist has really learned how to evoke responses that are usually outside the patient's normal range of ego control. There

are vast individual differences to be taken into account. Some patients can easily accept *direct suggestions* simply because they believe so much in the therapist's "prestige" or "power." Such belief wipes away the limitations and doubts characteristic of their usual attitudes; they don't believe they can accomplish such and such by themselves, but their belief system allows them to accomplish it in the special circumstances of therapy.

Other patients, more critical and doubting, caught in a narrow, rationalistic view of themselves, require *indirect suggestions* that will bypass the destructive limitations of their belief system. Still other patients, more in tune with the facts, recognize their personal limitations but need not believe in the prestige or power of the therapist; rather, they hope the therapist really has the skill to help them accomplish their goal by indirect suggestions whose rationale they need not understand at the time. It is in the invention and practice of indirect suggestion for the average or "resistant" ("limited" would be a better word) patient that Erickson has excelled. We will now make an effort to catalog those indirect approaches to suggestion.

b. Indirect Approaches to Hypnotic Suggestion

Wetterstrand (1902), who was one of Bernheim's foremost students, described the problem of suggestion in a manner that places Erickson's indirect approaches in proper historical perspective.

> Suggestion, or rather suggestibility, is composed of two elements: ability to receive an impulse from without, and the ideo-plastic faculty. [The power that ideas possess to influence physiological conditions.] As these are absolutely independent of each other, we must distinguish between them. There are patients who are very impressionable, and who accept a suggested idea with absolute confidence; the influence, however, of the idea upon their physiological functions is feeble. They do not realize the suggestions, and their morbid symptoms yield with great difficulty, as their ideo-plastic conception is small. Others, on the contrary, accept suggestions slowly, are incredulous and even resist them. Nevertheless we find that the physiological and pathological processes are easily modified by the psychic influence, sometimes by autosuggestions.

In keeping with this dichotomy, Erickson's indirect approaches may be divided into two similar categories:

1. *Structuring an acceptance set* to facilitate the acceptance of the "suggested idea."
2. *Utilizing the patient's associative processes and mental skills* to facilitate the "ideo-plastic faculty."

1. Structuring an Acceptance Set. Every therapist has innumerable approaches for facilitating an atmosphere of cooperation, receptivity, and the possibility of creativity within the therapy session. Here we will only list the hypnotic forms that we have found in prominent use by Erickson in the actual process of trance induction and the facilitation of hypnotic responses. The index is keyed to illustrations and discussions of all of these hypnotic forms for facilitating an acceptance set.

The "yes set"

Truisms and tautologies

Use of interesting and personally motivating material

Intercontextual cues and suggestions

Interspersal technique

Obtaining patient's assent

Casual, permissive, and positive approach

Vocal intonations of sincerity and intentness

Validating and ratifying suggestions

Covering all possibilities of response

Accepting all responses as valid

Building expectancy

2. Utilizing the Patient's Associative Structure and Mental Skills. Erickson's work is rich in hypnotic forms designed to utilize a patient's own associative structure and mental processes to facilitate the "ideo-plastic faculty."

Not all of these hypnotic forms are original with Erickson. The evocation of hypnotic phenomena by asking pointed questions, for example, is a classical approach much utilized by Braid (1846) to evoke hallucinatory phenomena in all sense modalities even while patients were apparently awake. The invention and systematic use of a variety of these hypnotic forms for *the study and utilization of a patient's own associative structure and mental skills in ways that are outside his usual range of conscious ego control to effect therapeutic goals,* however, does appear to be one of Erickson's original contributions to the theory and practice of "suggestion." The use of these hypnotic forms is by now so much a part of Erickson's nature that Rossi sometimes felt "woozy" and a bit in a trance even while apparently having a straightforward intellectual discussion with Erickson. Erickson himself is not always clear about the means by which his "conversation" is effective in structuring and directing a listener's associative processes in predetermined ways. Erickson maintains that fixing and focusing attention by such conversation does put the listener into trance without the need for any other formal process of induction. As we have repeatedly seen in this volume, a single sentence uttered by Erickson can be loaded with a number of hypnotic forms that catch the listener's mental fabric in various ways. In this volume it has been our precarious task to make a beginning in untangling, uncovering, and labeling some of these indirect hypnotic forms, which are listed below:

Apposition of opposites

Binds and double binds

Compound suggestions

Contingent suggestions

Covering all possibilities of a class of responses

Dissociation

Ideomotor signaling

Implication

Implied directive

Intercontextual cues and suggestions

Multiple levels of communication (analogy,

Multiple tasks and serial suggestions

Not doing, not knowing

Open-ended suggestions

Pantomime and nonverbal suggestions

Paradoxical intention

Partial remarks and dangling phrases

Questions

Surprise

Truisms

Utilizing need for closure

Voice locus and dynamics

Yes set

puns, metaphor, etc.)

These hypnotic forms are all merely descriptive labels of different aspects of suggestion; they need not function independently of one another. One and the same suggestion, for example, could be a truism (because it is true), a compound suggestion (because it contains at least two connected statements), and an implication (because it implies that more than one may be immediately apparent). In fact, the art of formulating suggestions is to utilize as many of these mutually reinforcing hypnotic forms as possible in close proximity.

It is important to repeat that while Erickson does think of trance as a special state, he does not believe hypersuggestibility is a necessary characteristic of trance. That is, just because patients experience trance, it does not mean they are going to accept the therapist's suggestions. This is a major misconception that has frustrated and discouraged many workers in the past and has impeded the development of hypnosis as a science. Trance is a special state that intensifies the therapeutic relationship and focuses patients' attention on inner realities. *Trance does not ensure the acceptance of suggestions.* Erickson depends on the above approaches to evoke and move patients' associative processes and mental skills in certain directions to *sometimes* achieve certain goals. So-called suggestion is actually this process of evoking and utilizing a patient's own associations, mental skills, and mental mechanisms.

How shall we conceptualize the hypnotic forms listed above? Obviously, they are communication devices of sorts. They are all bits and pieces of the new science of pragmatics: the relation between signs and the users of signs. Since these communication devices have all been developed in clinical practice, there is an urgent need to validate them and study their parameters in controlled laboratory studies as well as in further clinical and field experiments. There appears to be an infinite expanse of exploration awaiting future workers in this area. Undoubtedly the field will continue to expand and change just as human consciousness itself develops in new ways.

THE FACILITATION OF HUMAN POTENTIALS

Throughout this volume we have touched upon the various means by which human potentials and unrealized abilities may be explored and facilitated during trance. Trance in this sense can be understood as a period of free exploration and learning unencumbered by some of the limitations of a person's previous history. It is for this purpose that Erickson developed so many unique approaches to hypnotic induction and trance training wherein a person's usual limitations could be altered momentarily so that inner potentials could become manifest. The great variety of these approaches can never become standardized because happy humans are never static and standardized. Everyone is an individual in a process of development. The hypnotic interaction reflects and facilitates this development in ways that are creative and surprising to both therapists and patients. Well-trained hypnotherapists are, above all, fine observers who are able to recognize the fetters that bind human nature. They are ever eager to make available means of freeing and facilitating human development. They then wisely stand aside to watch and wonder about its ultimate course.

Foreword

Speak to the wall so the door may hear - *Sufi saying.*

Everyone who knows Milton Erickson is aware that he rarely does anything without a purpose. In fact, his goal-directedness may be the most important characteristic of his life and work.

Why is it, then, that prior to writing *Hypnotic Realities* with Ernest Rossi (Irvington, 1976) he had avoided presenting his work in book form? Why did he choose Ernest Rossi to coauthor that book and the present one? And, finally, I could not help but wonder, Why did he ask me to write this foreword?

Erickson has, after all, published almost 150 articles over a fifty-year period, but only two relatively minor books - *Time Distortion in Hypnosis,* written in 1954 with L. S. Cooper, and *The Practical Applications of Medical and Dental Hypnosis,* in 1961 with S. Hershman, MD and I. I. Sector, DDS. It is easy to understand that in his seventies he may well be eager to leave a legacy, a definitive summing up, a final opportunity for others to really understand and perhaps emulate him.

Rossi is an excellent choice as a coauthor. He is an experienced clinician who has trained with many giants in psychiatry - Franz Alexander, amongst others. He is a Jungian training analyst. He is a prolific author and has devoted the major part of his time over the past six years to painstaking observation, recording and discussion of Erickson's work.

Again, Why me? I am also a training analyst, but with a different group - the American Institute of Psychoanalysis (Karen Horney). I have been a practicing psychiatrist for almost thirty years. For almost fifteen years I have also done a great deal of work with disabled patients. I have been involved with hypnosis for over thirty-five years, since I first heard about Milton Erickson, who was then living in Eloise, Michigan.

Both Rossi and I have broad, but differing, clinical and theoretical backgrounds. Neither of us has

worked primarily with hypnosis. Therefore, neither of us has a vested interest in promoting some hypnotic theories of our own. We are genuinely devoted to the goal of presenting Erickson's theories and ideas, not only to practitioners of hypnosis, but to the community of psychotherapists and psychoanalysts which has had little familiarity with hypnosis. Towards this end, Rossi assumes the posture of a rather naive student acting on behalf of the rest of us.

Margaret Mead, who also counts herself as one of his students, writes of the originality of Milton Erickson in the issue of *The American Journal of Clinical Hypnosis*dedicated to him on his seventy-fifth birthday (Mead, M. The Originality of Milton Erickson, *AJCH,* Vol. 20, No. 1, July 1977, pp. 4-5). She comments that she has been interested in his originality ever since she first met him in the summer of 1940, expanding on this idea by stating, It can be firmly said that Milton Erickson never solved a problem in an old way if he can think of a new way - and he usually can. She feels, however, that his unquenchable, burning originality was a barrier to the transmission of much of what he knew and that inquiring students would become bemused with the extraordinary and unexpected quality of each different demonstration, lost between trying to imitate the intricate, idiosyncratic response and the underlying principles which he was illuminating. In *Hypnotic Realities* and in this book, Ernest Rossi takes some large steps towards elucidating these underlying principles. He does this most directly by organizing and extracting them from Erickson's case material. Even more helpfully, though, he encourages Erickson to spell out some of these principles.

Students who study this volume carefully, as I did, will find that the authors have done the best job to date in clarifying Erickson's ideas on the nature of hypnosis and hypnotic therapy, on techniques of hypnotic induction, on ways of inducing therapeutic change, and of validating this change. In the process they have also revealed a great deal of helpful data about Erickson's philosophy of life and therapy. Many therapists, both psychoanalytic and others, will find his approaches compatible with their own and far removed from their preconceptions about hypnosis. As the authors point out, Hypnosis does not change the person nor does it alter past experiential life. It serves to permit him to learn more about himself and to express himself more adequately. . . . Therapeutic trance helps people side-step their own learned limitations so that they can more fully explore and utilize their potentials.

Those who read Erickson's generous offering of fascinating case histories, and then attempt to emulate him, will undoubtedly find that they do not achieve results that are at all comparable to his. They may then give up, deciding that Erickson's approach is one that is unique for him. They may note that Erickson has several handicaps that have always set him apart from others, and that may certainly permit him to have a unique way of viewing and responding. He was born with color deficient vision, tone deafness, dyslexia, and lacking a sense of rhythm. He suffered two serious attacks of crippling poliomyelitis. He has been wheelchair bound for many years from the effects of the neurological damage, supplemented by arthritis and myositis. Some will not be content with the rationalization that Erickson is a therapeutic or inimitable genius. And they will find that with the help of clarifiers and facilitators, such as Ernest Rossi, there is much in his way of working that can be learned, taught and utilized by others.

Erickson himself has advised, in *Hypnotic Realities* (page 258), In working at a problem of

difficulty, you try to make an interesting design in the handling of it. That way you have an answer to the difficult problem. Become interested in the design and don't notice the back-breaking labor. In dealing with the difficult problem of analyzing and teaching Erickson's approaches, Rossi's designs can be most helpful. Whether each reader will choose to accept Rossi's suggestion that he practice the exercises recommended in this book, is an individual matter; in my experience, it has been worthwhile to practice some of them. In fact, by deliberately and planfully applying some of Erickson's approaches as underlined by Rossi, I found that I have been able to help patients experience deeper states of trance and be more open to changing as an apparent consequence of this. I found that setting up therapeutic double binds, giving indirect posthypnotic suggestions, using questions to facilitate therapeutic responsiveness, and building up compound suggestions have been particularly helpful. Erickson and Rossi's repeated emphasis on what they call the utilization approach is certainly justified. In this book they give many vivid and useful examples of accepting and utilizing the patient's manifest behavior, utilizing the patient's inner realities, utilizing the patient's resistances, and utilizing the patient's negative affect and symptoms. Erickson's creative use of jokes, puns, metaphors and symbols has been analyzed by others, notably Haley and Bandler and Grinder, but the examples and discussion in this book add a great deal to our understanding.

At times, Erickson will work with a patient in a light trance, in what he calls a common everyday trance, or no trance at all. He does not limit himself to short-term therapy. This is illustrated in his painstaking work over a nine-month period with Pietro, the flutist with the swollen lip, described in one of the dramatic case outlines in this book. His expertise, however, in working with patients in the deepest trances, often with amnesia for the therapeutic work, has always interested observers. The question of whether or not inducing deeper trances, and giving directions or suggestions indirectly rather than directly, leads to more profound or lasting clinical results is a researchable one. It has certainly been my experience that if one does not believe in, or value, deeper trances and does not strive for them, one is not likely to see them very often. My experience has also been that the achievement of deeper trances, often including phenomena such as dissociation, time distortion, amnesia, and age-regression, *does* lead to quicker and apparently more profound changes in patients' symptoms and attitudes.

Erickson emphasizes the value of helping patients to work in the mode of what he would call the unconscious. He values the wisdom of the unconscious. In fact, he often goes to great lengths to keep the therapeutic work from being examined and potentially destroyed by the patient's conscious mind and by the patient's learned and limited sets. His methods of doing this are more explicitly outlined in this book than in any other writings available to date.

It is true that he tends not to distinguish between induction of trance or hypnotic techniques and therapeutic techniques or maneuvers. He feels that it is a waste of time for the therapist to use meaningless, repetitious phrases in the induction of trance as this time might be more usefully employed injecting therapeutic suggestions or in preparing the patient for change. As Rossi has pointed out, both the therapy and trance, induction involve, in the early stages, a depotentiation of the patient's usual and limited mental sets. Erickson is never content with simply inducing a trance, but is always concerned with some therapeutic role.

He points out the limited effectiveness of direct suggestion, although he is certainly aware that hypnotic techniques, using direct suggestion, will frequently enhance the effectiveness of behavior modification approaches such as desensitization and cognitive retraining. He notes that Direct suggestion . . . does not evoke the re-association and reorganization of ideas, understandings and memories so essential for an actual cure . . . Effective results in hypnotic psychotherapy . . . derive only from the patient's activities. The therapist merely stimulates the patient into activity, often not knowing what that activity may be. And then he guides the patient and exercises clinical judgment in determining the amount of work to be done to achieve the desired results (Erickson, 1948). From this comment, and from reading the case histories in this volume and in other publications, it should be apparent that Erickson demands and evokes much less doctrinal compliance than do most therapists.

It is obvious that clinical judgment comes only as the result of many years of intensive study of dynamics, pathology and health, and from actually working with patients.

The judgment of the therapist will also be influenced by his own philosophy and goals in life. Erickson's own philosophy is manifested by his emphasis on concepts such as growth and delight and joy . To this he adds, Life isn't something you can give an answer to today. You should enjoy the process of waiting, the process of becoming what you are. There is nothing more delightful than planting flower seeds and not knowing what kinds of flowers are going to come up. My own experience in this regard is illustrated by my having visited him in 1970, spending a four-hour session with him, and leaving with the feeling that I had spent this time mostly in listening to stories about his family and patients. I did not see him again until the summer of 1977. Then, at 5:00 a.m. in a Phoenix motel, while I was reviewing some tapes of Erickson at work, some very important insights became vividly evident to me. They were obviously related to work begun during our session in 1970 and to self analysis I had done in the intervening seven years. Later that morning when I excitedly mentioned these insights to Erickson, he, typically, simply smiled and did not attempt to elaborate on them in any way.

When we read some of the writings on other forms of therapy, such as family therapy or Gestalt therapy, we are struck by how much they have been influenced by Erickson. This is no accident as many of the early therapists in these schools began working with hypnosis or even with Erickson himself. I hope that Rossi will trace some of these influences in his future writings. I have alluded to some of them in my article, Recent Experiences with Encounter Gestalt and Hypnotic Techniques (Rosen, S. *Am J. Psychoanalysis,* Vol. 32, No. 1, 1972, pp. 90-105).

In conjunction with Erickson and Rossi's first volume *Hypnotic Realities, Hypnotherapy: An Exploratory Casebook* should serve as a firm basis for courses in Ericksonian therapy or Ericksonian hypnosis. These courses may be supplemented by other books, including those written by J. Haley and by Bandler and Grinder. In addition, we are now fortunate to have available a bibliography of the 147 articles written by Erickson himself (see Gravitz, M.A. and Gravitz, R. F., Complete Bibliography 1929-1977," *American Journal of Clinical Hypnosis,* 1977, *20,* 84-94).

Rossi has told me that in working with Erickson he has always been struck by the fact that

Erickson seems to be atheoretical. I have noted that this applies to Erickson's openness but certainly not to his emphasis on growth or his humanistic or socially oriented views. Rossi and others are constantly rediscovering the fact that Erickson always works towards goals - those of his patients', not his own. This may not seem to be such a revolutionary idea today when it is the avowed intention of almost all therapists, but perhaps many of us are limited in our capacity to carry out this intent. It is significant that both intent and practice are most successfully coordinated and realized in the work of this man who is probably the world's master in clinical hypnosis, and yet hypnosis is still associated by almost everyone with manipulation and suggestion - a typical Ericksonian paradox. The master manipulator allows and stimulates the greatest freedom!

Sidney Rosen, MD

New York

Preface

The present work is the second in a series of volumes by the authors that began with the publication *of Hypnotic Realities* (Irvington, 1976). Like that first volume, the present work is essentially the record of the senior author's efforts to train the junior author in the field of clinical hypnotherapy. As such, the present work is not of an academic or scholarly nature but rather a practical study of some of the attitudes, orientations, and skills required of the modern hypnotherapist.

In the first chapter we outline the utilization approach to hypnotherapy as the basic orientation to our work. In the second chapter we essay a more systematic presentation of the indirect forms of suggestion, which were originally selected out of the case presentations of our first volume. We now believe that the *utilization approach* and the *indirect forms of suggestion* are the essence of the senior author's therapeutic innovations over the past fifty years and account for much of his unique skill as a hypnotherapist.

In Chapter Three we illustrate how the utilization approach and the indirect forms of suggestion can be integrated to facilitate the induction of therapeutic trance in a manner that simultaneously orients the patient toward therapeutic change. In our fourth chapter we illustrate the approaches to posthypnotic suggestion that the senior author has found most effective in day-to-day clinical practice.

These first four chapters outline some of the basic principles of the senior author's approach. We hope this presentation will provide other clinicians with a broad and practical perspective of the

senior author's work and serve as a source of hypotheses about the nature of therapeutic trance that will be tested with more controlled experimental studies by researchers.

At the end of each of these first four chapters we have suggested a number of exercises to facilitate learning the orientation, attitudes, and skills required of anyone who wants to put some of this material into actual practice. A simple reading and understanding of the material is not enough. An extensive effort to acquire new habits of observation and interpersonal interaction are required. All the suggested exercises have been put into practice as we have sought to hone our own skills and teach others.

Each of the remaining six chapters presents case studies illustrating and further exploring the senior author's clinical work with patients. Six of these cases (cases 1,5,8,10,11, and 12) are major studies like those in our first volume, *Hypnotic Realities,* where we transcribed tape recordings of the senior author's actual words and patterns of interaction with patients. The recording equipment for these studies was provided by a research grant from the American Society of Clinical Hypnosis - Education and Research Foundation. In our commentaries on these sessions we have presented our current understanding of the dynamics of the hypnotherapeutic process and discussed a number of issues such as the facilitation of the creative process and the functions of the left and right hemispheres.

Most of the other shorter cases were drawn from the senior author's file of unpublished records of his work in private practice, some of them from long-unopened folders containing yellowed pages more than a quarter of a century old. These cases were all reviewed and re-edited with fresh commentaries and provide an appropriate perspective on the spontaneous creativity and daring required of the hypnotherapist in clinical practice. In addition, we have skimmed through many tape recordings of the senior author's lectures and workshops at the meetings of the American Society of Clinical Hypnosis. Some of these were already typed and partially edited by Florence Sharp, Ph.D., and other members of the Society. Most of these appear under the heading Selected Shorter Cases: Exercises for Analysis. Many of them have been repeated and published so often (Haley, 1973) that they appear anecdotal, as part of the folklore of hypnosis in the past half-century. They can serve as marvelous exercises for analysis, however. At the end of each such case we have placed in italics some of the principles we feel were involved. The reader may enjoy finding others.

It is our impression that the clinical practice of hypnotherapy is currently emerging from a period of relative quiescence into an exciting time of new discoveries and fascinating possibilities. Those who know the history of hypnosis are already familiar with this cyclic pattern of excitement and quiescence that is so characteristic of the field. Some historians of science now believe this cyclic pattern is characteristic of all branches of science and art: The excitement comes with periods of new discovery, the quiescence comes as these are assimilated. As the junior author gradually put this volume together, he frequently had a subjective sense of new discovery. But was it new only for him, or would it be new for others as well? We must rely upon you, our reader, to make an independent assessment of the matter and perhaps carry the work a step further.

Milton H. Erickson, M.D. Ernest L. Rossi, Ph.D.

Acknowledgments

This work can be recognized as a truly community effort, with many more individuals contributing to it than we can acknowledge by name. First among these are our patients, who frequently recognized and cooperated with the exploratory nature of our work with them. Their spontaneous creativity is truly the basis of all innovative therapeutic work: We simply report what they learned to do with the hope that their success may be a useful guide for others.

Many of the teachers and participants in the seminars and workshops of the *American Society of Clinical Hypnosis* have provided a continual series of insights, illustrations, and comments that have found their way into this work. Prominent among these are Leo Alexander, Ester Bartlett, Franz Baumann, Neil D. Capua, David Cheek, Sheldon Cohen, Jerry Day, T. E. A. Von Dedenroth, Roxanne and Christie Erickson, Fredericka Freytag, Melvin Gravitz, Frederick Hanley, H. Clagett Harding, Maurice McDowell, Susan Mirow, Marion Moore, Robert Pearson, Bertha Rodger, Florence Sharp, Kay Thompson, Paul Van Dyke, M. Erik Wright.

To Robert Pearson we owe a special acknowledgment for having first suggested the basic format of this work, for his continual encouragement during its gestation, and for his critical reading of our final draft. Ruth Ingham and Margaret Ryan have contributed significant editing skills that finally enabled our work to reach the press.

Finally, we wish to acknowledge the following publishers who have generously permitted the republication of five of the papers in this volume: American Society of Clinical Hypnosis, Journal Press, W. B. Saunders Company, and Springer Verlag.

CHAPTER 1

The Utilization Approach to Hypnotherapy

We view hypnotherapy as a process whereby we help people utilize their own mental associations, memories, and life potentials to achieve their own therapeutic goals. Hypnotic suggestion can facilitate the utilization of abilities and potentials that already exist within a person but that remain unused or underdeveloped because of a lack of training or understanding. The hypnotherapist carefully explores a patient's individuality to ascertain what life learnings, experiences, and mental skills are available to deal with the problem. The therapist then facilitates an approach to trance experience wherein the patient may utilize these uniquely personal internal responses to achieve therapeutic goals.

Our approach may be viewed as a three-stage process: (1) a period of *preparation*during which the therapist explores the patients repertory of life experiences and facilitates constructive frames of reference to orient the patient toward therapeutic change; (2) an activation and utilization of the patient's own mental skills during a period *of therapeutic trance;* (3) a careful *recognition, evaluation, and ratification of the therapeutic change* that takes place. In this first chapter we will introduce some of the factors contributing to the successful experience of each of these three stages. In the chapters that follow we will illustrate and discuss them in greater detail.

1. Preparation

The initial phase of hypnotherapeutic work consists of a careful period of observation and preparation. Initially the most important factor in any therapeutic interview is to establish a sound rapport - that is, a positive feeling of understanding and mutual regard between therapist and patient. Through this rapport therapist and patient together create a new therapeutic frame of reference that will serve as the growth medium in which the patient's therapeutic responses will develop. The rapport is the means by which therapist and patient secure each others' attention. Both develop a yes set, or acceptance of each other. The therapist presumably has a well developed ability to observe and relate; the patient is learning to observe and achieve a state of *response attentiveness ,* that state of extreme attentiveness in responding to the nuances of communication presented by the therapist.

In the initial interview the therapist gathers the relevant facts regarding the patient's problems and the *repertory of life experiences and learnings that will be utilized for therapeutic purposes.* Patients have problems because of learned limitations. They are caught in mental sets, frames of reference, and belief systems that do not permit them to explore and utilize their own abilities to best advantage. Human beings are still in the process of learning to use their potentials. The therapeutic transaction ideally creates a new phenomenal world in which patients can explore their potentials, freed to some extent from their learned limitations. As we shall later see, *therapeutic*

trance is a period during which patients are able to break out of their limited frameworks and belief systems so they can experience other patterns of functioning within themselves. These other patterns are usually response potentials that have been learned from previous life experience but, for one reason or another, remain unavailable to the patient. The therapist can explore patients' personal histories, character, and emotional dynamics, their field of work, interests, hobbies, and so on to assess the range of life experiences and response abilities that may be available for achieving therapeutic goals. Most of the cases in this book will illustrate this process.

As the therapist explores the patient's world and facilitates rapport, it is almost inevitable that *new frames of reference and belief systems are created.* This usually happens whenever people meet and interact closely. In hypnotherapy this spontaneous opening and shifting of mental frameworks and belief systems is carefully studied, facilitated, and utilized. The therapist is in a constant process of evaluating what limitations are at the source of the patient's problem and what new horizons can be opened to help the patient outgrow those limitations. In the preparatory phase of hypnotherapeutic work mental frameworks are facilitated in a manner that will enable the patient to respond to the suggestions that will be received later during trance. Suggestions made during trance frequently function like keys turning the tumblers of a patient's associative processes within the locks of certain mental frameworks that have already been established. A number of workers (Weitzenhoffer, 1957, Schneck, 1970, 1975) have described how what is said before trance is formally induced can enhance hypnotic suggestion. We agree and emphasize that effective trance work is usually preceded by a preparatory phase during which we help patients create an optimal attitude and belief system for therapeutic responses.

A singularly important aspect of this optimal attitude is *expectancy.* Patients' expectations of therapeutic change permits them to suspend the learned limitations and negative life experiences that are at the source of their problems. A suspension of disbelief and an extraordinarily high expectation of cure has been used to account for the miraculous healing sometimes achieved within a religious belief system. As will be seen in our overall analysis of the dynamics of therapeutic trance in the following section, such seemingly miraculous healing can be understood as a special manifestation of the more general process we utilize to facilitate therapeutic responses in hypnotherapy.

2. Therapeutic Trance

Therapeutic trance is a period during which the limitations of one's usual frames of reference and beliefs are temporarily altered so one can be receptive to other patterns of association and modes of mental functioning that are conducive to problem-solving. We view the dynamics of trance induction and utilization as a very personal experience wherein the therapist helps patients to find their own individual ways. Trance induction is not a standardized process that can be applied in the same way to everyone. There is no method or technique that always works with everyone or even with the same person on different occasions. Because of this we speak of approaches to trance experience. We thereby emphasize that we have many means of facilitating, guiding, or teaching how one might be led to experience the state of receptivity that we call therapeutic trance. However, we have no universal method for effecting the same uniform trance state in

everyone. Most people with problems can be guided to experience their own unique variety of therapeutic trance when they understand that it may be useful. The art of the hypnotherapist is in helping patients reach an understanding that will help them give up some of the limitations of their common everyday world view so that they can achieve a state of receptivity to the new and creative within themselves.

For didactic purposes we have conceptualized the dynamics of trance induction and suggestion as a five-stage process, outlined in Figure 1.

While we may use this paradigm as a convenient framework for analyzing many of the hypnotherapeutic approaches we will illustrate in this volume, it must be understood that the individual manifestations of the process will be just as unique and various as are the natures of the people experiencing it. We will now outline our understanding of these five stages.

Figure 1: A five-stage paradigm of the dynamics of trance induction and suggestion (from Erickson and Rossi, 1976.)

1 . Fixation of Attention	via	Utilizing the patient's beliefs and behavior for focusing attention on inner realities.
2. Depotentiating Habitual Frameworks and Belief Systems	via	Distraction, shock, surprise, doubt, confusion, dissociation, or any other process that interrupts the patient's habitual frameworks.
3. Unconscious Search	via	Implications, questions, puns, and other indirect forms of hypnotic suggestion.
4. Unconscious Process	via	Activation of personal associations and mental mechanisms by all the above.
5. Hypnotic Response	via	An expression of behavioral potentials that are experienced as taking place autonomously.

Fixation of Attention

The fixation of attention has been the classical approach for initiating therapeutic trance, or hypnosis. The therapist would ask the patient to gaze at a spot or candle flame, a bright light, a revolving mirror, the therapist's eyes, gestures, or whatever. As experience accumulated it became evident that the point of fixation could be anything that held the patient's attention. Further, the point of fixation need not be external; it is even more effective to focus attention on the patient's own body and inner experience. Thus approaches such as hand levitation and body relaxation were developed. Encouraging the patient to focus on sensations or internal imagery led attention inward even more effectively. Many of these approaches have become standardized and are well described in reference works on hypnosis (Weitzenhoffer, 1957; Hartland, 1966; Haley, 1967).

The beginner in hypnotherapy may well study these standardized approaches and closely follow some of them to initiate trance in a formalized manner. They are often highly impressive to the patient and very effective in inducing trance. Student therapists will be in error, however, if they attempt to utilize only one approach as the universal method and thereby blind themselves to the unique motivations and manifestations of trance development in each person. The therapist who carefully studies the process of attention in everyday life as well as in the consulting room will soon come to recognize that an interesting story or a fascinating fact or fantasy can fixate attention just as effectively as a formal induction. Anything that fascinates and holds or absorbs a person's attention could be described as hypnotic. We have the concept of the common everyday trance for those periods in everyday life when we are so absorbed or preoccupied with one matter or another that we momentarily lose track of our outer environment.

The most effective means of focusing and fixing attention in clinical practice is to recognize and acknowledge the patient's current experience. When the therapist correctly labels the patient's ongoing hereand-now experience, the patient is usually immediately grateful and open to whatever else the therapist may have to say. Acknowledging the patient's current reality thus opens a yes set for whatever suggestions the therapist may wish to introduce. This is the basis of the utilization approach to trance induction, wherein therapists gain their patients' attention by focusing on their current behavior and experiences (Erickson, 1958,1959). Illustrations of this utilization approach to trance induction will be presented in our third chapter.

Depotentiating Habitual Frameworks and Belief Systems

In our view one of the most useful psychological effects of fixating attention is that it tends to depotentiate patients' habitual mental sets and common everyday frames of reference. Their belief systems are more or less interrupted and suspended for a moment or two. Consciousness has been *distracted.* During that momentary suspension latent patterns of association and sensory-perceptual experience have an opportunity to assert themselves in a manner that can

initiate the altered state of consciousness that has been described as trance or hypnosis.

There are many means of depotentiating habitual frames of reference. Any experience of shock or surprise momentarily fixates attention and interrupts the previous pattern of association. Any experience of the unrealistic, the unusual, or the fantastic provides an opportunity for altered modes of apprehension. The authors have described how confusion, doubt, dissociation, and disequilibrium are all means of depotentiating patients' learned limitations so that they may become open and available for new means of experiencing and learning, which are the essence of therapeutic trance (Erickson, Rossi, and Rossi, 1976). The interruption and suspension of our common everyday belief system has been described by the junior author as a *creative moment* (Rossi, 1972a):

But what is a creative moment? Such moments have been celebrated as the exciting hunch by scientific workers and inspiration by people in the arts (Barron, 1969). *A creative moment occurs when a habitual pattern of association is interrupted;* there may be a spontaneous lapse or relaxation of one's habitual associative process; there may be a *psychic shock,* an overwhelming sensory or emotional experience; a psychedelic drug, a toxic condition or sensory deprivation may serve as the catalyst; yoga, Zen, spiritual and meditative exercises may likewise interrupt our habitual associations and introduce a momentary void in awareness. In that fraction of a second when the habitual contents of awareness are knocked out there is a chance for pure awareness, the pure light of the void (Evans-Wentz, 1960) to shine through. This fraction of a second may be experienced as a mystic state, satori, a peak experience or an altered state of consciousness (Tart, 1969). It may be experienced as a moment of fascination or falling in love when the gap in one's awareness is filled by the *new* that suddenly intrudes itself.

The*creative moment is thus a gap in one's habitual pattern of awareness.* Bartlett (1958) has described how the genesis of original thinking can be understood as the filling in of mental gaps. *The new that appears in creative moments is thus the basic unit of original thought and insight as well as personality change.* Experiencing a creative moment may be the phenomenological correlate of a critical change in the molecular structure of proteins within the brain associated with learning (Gaito, 1972; Rossi, 1973b), or the creation of new cell assemblies and phase sequences (Hebb, 1963).

The relation between psychological shock and creative moments is apparent: a psychic shock interrupts a person's habitual associations so that something new may appear. Ideally psychological shock sets up the conditions for a creative moment when a new insight, attitude, or behavior change may take place in the subject. Erickson (1948) has also described hypnotic trance itself as a special psychological state which effects a similar break in the patient's conscious and habitual associations so that creative learning can take place.

In everyday life one is continually confronted with difficult and puzzling situations that mildly shock and interrupt one's usual way of thinking. Ideally these problem situations will initiate a creative moment of reflection that may provide an opportunity for something new to emerge. Psychological problems develop when people do not permit the naturally changing circumstances of life to interrupt their old and no longer useful patterns of association and experience so that

new solutions and attitudes may emerge.

Unconscious Search and Unconscious Process

In everyday life there are many approaches to fixing attention, depotentiating habitual associations, and thereby initiating an *unconscious search* for a new experience or solution to a problem. In a difficult situation, for example, one may make a joke or use a pun to interrupt and reorganize the situation from a different point of view. One may use allusions or implications to intrude another way of understanding the same situation. Like metaphor and analogy (Jaynes, 1976) these are all means of momentarily arresting attention and requesting a search - essentially a search on an unconscious level - to come up with a new association or frame of reference. These are all opportunities for creative moments in everyday life wherein a necessary reorganization of one's experience takes place.

In therapeutic trance we utilize similar means of initiating a search on an unconscious level. These are what the senior author has described as the *indirect forms of sugg*estion (Erickson and Rossi, 1976; Erickson, Rossi, and Rossi, 1976). In essence, an indirect suggestion initiates an unconscious search and facilitates unconscious processes within patients so that they are usually somewhat surprised by their own responses. The indirect forms of suggestion help patients bypass their learned limitations so they are able to accomplish a lot more than they are usually able to. The indirect forms of suggestion are facilitators of mental asso*ciations and unconscious processes.* In the next chapter we will outline our current understanding of a variety of these indirect forms of suggestion.

The Hypnotic Response

The hypnotic response is the natural outcome of the unconscious search and processes initiated by the therapist. Because it is mediated primarily by unconscious processes within the patient, the hypnotic response appears to occur automatically or autonomously; it appears to take place all by itself in a manner that may seem alien or dissociated from the person's usual mode of responding on a voluntary level. Most patients typically experience a mild sense of pleasant surprise when they find themselves responding in this automatic and involuntary manner. That sense of surprise, in fact, can generally be taken as an indication of the genuinely autonomous nature of their response.

Hypnotic responses need not be initiated by the therapist, however. Most of the classical hypnotic phenomena, in fact, were discovered quite by accident as natural manifestations of human behavior that occurred spontaneously in trance without any suggestion whatsoever. Classical hypnotic phenomena such as catalepsy, anesthesia, amnesia, hallucinations, age regression, and time distortion are all spontaneous trance phenomena that were a source of amazement and bewilderment to early investigators. It was when they later attempted to induce trance and study trance phenomena systematically that these investigators found that they could suggest the various hypnotic phenomena. Once they found it possible to do this, they began to use suggestibility itself as a criterion of the validity and depth of trance experience.

When the next step was taken to utilize trance experience as a form of therapy, hypnotic suggestibility was emphasized even more as the essential factor for successful work. An unfortunate side effect of this emphasis on suggestibility was in the purported power of hypnotists to control behavior with suggestion. By this time our conception of hypnotic phenomena had moved very far indeed from their original discovery as natural and spontaneous manifestations of the mind. Hypnosis acquired the connotations of manipulation and control. The exploitation of naturally occurring trance phenomena as a demonstration of power, prestige, influence, and control (as it has been used in stage hypnosis) was a most unfortunate turn in the history of hypnosis.

In an effort to correct such misconceptions the senior author (Erickson, 1948) described the merits of direct and indirect suggestion in hypnotherapy as follows:

The next consideration concerns the general role of suggestion in hypnosis. Too often, the unwarranted and unsound assumption is made that, since a trance state is induced and maintained by suggestion, and since hypnotic manifestations can be elicited by suggestion, whatever develops from hypnosis must necessarily and completely be a result and primary expression of suggestion. Contrary to such misconceptions, the hypnotized person remains the same person. Only his behavior is altered by the trance state, but even so, that altered behavior derives from the life experience of the patient and not from the therapist. At the most, the therapist can influence only the manner of self-expression. The induction and maintenance of a trance serve to provide a special psychological state in which the patient can reassociate and reorganize his inner psychological complexities and utilize his own capacities in a manner concordant with his own experiential life. Hypnosis does not change the person, nor does it alter his past experiential life. It serves to permit him to learn more about himself and to express himself more adequately.

Direct suggestion is based primarily, if unwittingly, upon the assumption that whatever develops in hypnosis derives from the suggestions given. It implies that the therapist has the miraculous power of effecting therapeutic changes in the patient, and disregards the fact that therapy results from an inner resynthesis of the patient's behavior achieved by the patient himself. It is true that direct suggestion can effect an alteration in the patient's behavior and result in a symptomatic cure, at least temporarily. However, such a cure is simply a response to the suggestion and does not entail that reassociation and reorganization of ideas, understandings and memories so essential for an actual cure. It is this experience of reassociating and reorganizing his own experiential life that eventuates in a cure, not the manifestation of responsive behavior which can, at best, satisfy only the observer.

For example, anesthesia of the hand may be suggested directly and a seemingly adequate response may be elicited. However, if the patient has not spontaneously interpreted the command to include a realization of the need for inner reorganization, that anesthesia will fail to meet clinical tests and will be a pseudo-anesthesia.

An effective anesthesia is better induced, for example, by initiating a train of mental activity within the patient himself by suggesting that he recall the feeling of numbness experienced after a local anesthetic, or after a leg or arm went to sleep, and then suggesting that he can now experience a

similar feeling in his hand. By such an indirect suggestion the patient is enabled to go through those difficult inner processes of disorganizing, reorganizing, reassociating and projecting inner real experience to meet the requirements of the suggestion. Thus, the induced anesthesia becomes a part of his experiential life, instead of a simple, superficial response.

The same principles hold true in psychotherapy. The chronic alcoholic can be induced by direct suggestion to correct his habits temporarily, but not until he goes through the inner process of reassociating and reorganizing his experiential life can effective results occur.

In other words, hypnotic psychotherapy is a learning process for the patient, a procedure of reeducation. Effective results in hypnotic psychotherapy, or hypnotherapy, derive only from the patient's activities. The therapist merely stimulates the patient into activity, often not knowing what that activity may be, and then he guides the patient and exercises clinical judgment in determining the amount of work to be done to achieve the desired results. How to guide and to judge constitute the therapist's problem while the patient's task is that of learning through his own efforts to understand his experiential life in a new way. Such reeducation is, of course, necessarily in terms of the patient's life experiences, his understandings, memories, attitudes and ideas, and it cannot be in terms of the therapist's ideas and opinions.

In our work, therefore, we prefer to emphasize how therapeutic trance helps people sidestep their own learned limitations so that they can more fully explore and utilize their potentials. The hypnotherapist makes many approaches to altered states of functioning available to the patient. Most patients really cannot direct themselves consciously in trance experience because such direction can come only from their previously learned habits of functioning which are inhibiting the full utilization of their potentials. Patients must therefore learn to allow their own unconscious response potentials to become manifest during trance. The therapist, too, must depend upon the patient's unconscious as a source of creativity for problem-solving. The therapist helps the patient find access to this creativity via that altered state we call therapeutic trance. Therapeutic trance can thus be understood as a free period of psychological exploration wherein therapist and patient cooperate in the search for those hypnotic responses that will lead to therapeutic change. We will now turn our attention to the evaluation and facilitation of that change.

3. Ratification of Therapeutic Change

The recognition and evaluation of altered patterns of functioning facilitated by therapeutic trance is one of the most subtle and important tasks of the therapist. Many patients readily recognize and admit changes that they have experienced. Others with less introspective ability need the therapist's help in evaluating the changes that have taken place. A recognition and appreciation of the trance work is necessary, lest the patient's old negative attitudes disrupt and destroy the new therapeutic responses that are still in a fragile state of development.

The Recognition and Ratification of Trance

Different individuals experience trance in different ways. The therapist's task is to recognize these

individual patterns and when necessary point them out to patients to help verify or ratify their altered state of trance. Consciousness does not always recognize its own altered states. How often do we not recognize that we are actually dreaming? It is usually only after the fact that we recognize we were in a state of reverie or daydreaming. The inexperienced user of alcohol and psychedelic drugs must also learn to recognize and then go with the altered state in order to enhance and fully experience its effects. Since therapeutic trance is actually only a variation of the common everyday trance or reverie that everyone is familiar with but does not necessarily recognize as an altered state, some patients will not believe they have been affected in any way. For these patients, in particular, it is important to ratify trance as an altered state. Without this proof the patient's negative attitudes and beliefs can frequently undo the value of the hypnotic suggestion and abort the therapeutic process that has been initiated.

Because of this we will list in Table 1 some of the common indicators of trance experience which we have previously discussed and illustrated in some detail (Erickson, Rossi, and Rossi, 1976). Because trance experience is highly individualized, patients will manifest these indicators in varying combinations as well as in different degrees.

TABLE 1

SOME COMMON INDICATORS OF TRANCE EXPERIENCE

Autonomous Ideation and Inner Experience	Respiration
	Swallowing
	Startle reflex
Balanced Tonicity (Catalepsy)	
Body Immobility	Objective and Impersonal Ideation

Body Reorientation After Trance

Changed Voice Quality

Comfort, Relaxation

Economy of Movement

Expectancy

Eye Changes and Closure

Facial Features Smooth Relaxed

Feeling Distanced or Dissociated

Psychosomatic Responses

Pupillary Changes

Response Attentiveness

Sensory, Muscular Body Changes

(Paresthesias)

Slowing Pulse

Spontaneous Hypnotic Phenomena

Amnesia

Anesthesia

Body Illusions

	Catalepsy
Feeling Good After Trance	Regression
	Time Distortion
Literalism	etc.
Loss or Retardation of Reflexes	Time Lag in Motor and Conceptual
Blinking	Behavior

Most of these indicators will be illustrated as they appear in the cases of this book.

We look upon the spontaneous development of hypnotic phenomena such as age regression, anesthesia, catalepsy, and so on as more genuine indicators of trance than when these same phenomena are suggested. When they are directly suggested, we run into the difficulties imposed by the patient's conscious attitudes and belief system. When they come about spontaneously, they are the natural result of the dissociation or reorganization of the patient's usual frames of reference and general reality orientation which is characteristic of trance.

Certain investigators have selected some of these spontaneous phenomena as defining characteristics of the fundamental nature of trance. Meares (1957) and Shor (1959), for example, have taken regression as a fundamental aspect of trance. From our point of view, however, regression per se is not a fundamental characteristic of trance, although it is often present as an epiphenomenon of the early stage of trance development, when patients are learning to give up their usual frames of reference and modes of functioning. In this first stage of learning to experience an altered state, many uncontrolled things happen, including spontaneous age regression, paresthesias, anesthesias, illusions of body distortion, psychosomatic responses, time distortion, and so on. Once patients learn to stablize these unwanted side reactions, they can then allow their unconscious minds to function freely in interacting with the therapist's suggestions

without some of the limitations of their usual frames of reference.

Ideomotor and Ideosensory Signaling

Since much hypnotherapeutic work does not require a dramatic experience of classical hypnotic phenomena, it is even more important that the therapist learn to recognize the minimal manifestations of trance as alterations in a patient's *sensory-perceptual, emotional,* and *cognitive* functioning. A valuable means of evaluating these changes is in the use of ideomotor and ideosensory signaling (Erickson, 1961; Cheek and Le Cron, 1968). An experience of trance as an altered state can be ratified by requesting any one of a variety of ideomotor responses as follows:

If you have experienced some moments of trance in our work today, your right hand (or one of your fingers) can lift all by itself.

If you have been in trance today without even realizing it, your head will nod yes (or your *eyes* will close) all by itself.

The existence of a therapeutic change can be signaled in a similar manner.

If your unconscious no longer needs to have you experience (whatever symptom), your head will nod.

Your unconscious can review the reasons for that problem, and when it has given your conscious mind its source in a manner that is comfortable for you to discuss, your right index finger can lift all by itself.

Some subjects experience ideosensory responses more easily than other subjects. They may thus experience a feeling of lightness, heaviness, coolness, or prickliness in the designated part of the body.

In requesting such responses we are presumably allowing the patient's unconscious to respond in a manner that is experienced as involuntary by the patient. This involuntary or autonomous aspect of the movement or feeling is an indication that it comes from a response system that is somewhat dissociated from the patient's habitual pattern of voluntary or intentional response. The patient and therapist thus have indication that something has happened independently of the patient's conscious will. That something may be trance or whatever therapeutic response was desired.

An uncritical view of ideomotor and ideosensory signaling takes such responses to be the true voice of the unconscious. At this stage of our understanding we prefer to view them as only another response system that must be checked and crossed-validated just as any other verbal or nonverbal response system. We prefer to evoke ideomotor responses in such a manner that the patient's conscious mind may not witness them (for example, having eyes closed or averted when a finger or hand signal is given). It is very difficult, however, to establish that the conscious mind is unaware of what response is given and that the response is in fact given independently of conscious intention. Some patients feel that the ideomotor or ideosensory response is entirely on

an involuntary level. Others feel they must help it or at least know ahead of time what it is to be.

A second major use of ideomotor and ideosensory signaling is to help patients restructure their belief system. Doubts about therapeutic change may persist even after an extended period of exploring and dealing with a problem in trance. These doubts can often be relieved when the patient believes in ideomotor or ideosensory responses as an independent index of the validity of therapeutic work. The therapist may proceed, for example, with suggestions as follows:

If your unconscious acknowledges that a process of therapeutic change has been initiated, your head can nod.

When you know you need no longer be bothered by that problem, your index finger can lift, or get warm [or whatever].

In such usage there is value, of course, in having the patient's conscious mind recognize the positive response. The more autonomous or involuntary the ideomotor or ideosensory response, the more convincing it is to the patient.

At the present time we have no way of distinguishing when an ideomotor or ideosensory response is (1) a reliable and valid index of something happening in the unconscious (out of the patient's immediate range of awareness), or (2) simply a means of restructuring a conscious belief system. A great deal of carefully controlled experimental work needs to be done in this area. It is still a matter of clinical judgment to determine which process, or the degree to which both processes, are operating in any individual situation.

Summary

Our utilization approach to hypnotherapy emphasizes that therapeutic trance is a means by which we help patients learn to use their mental skills and potentials to achieve their own therapeutic goals. While our approach is patient-centered and highly dependent on the momentary needs of the individual, there are three basic phases that can be outlined and discussed for didactic purposes: Preparation, Therapeutic Trance, and Ratification of Therapeutic Change.

The goal of the initial preparatory period is to establish an optimal frame of reference to orient the patient toward therapeutic change. This is facilitated by the following factors, which were discussed in this chapter and which will be illustrated in the cases of this book.

Rapport

Response Attentiveness

Assessing Abilities to Be Utilized

Facilitating Therapeutic Frames of Reference

Creating Expectancy

Therapeutic trance is a period during which the limitations of one's habitual frames of reference are temporarily altered so that one can be receptive to more adequate modes of functioning. While the experience of trance is highly variable, the overall dynamics of therapeutic trance and suggestion could be outlined as a five-stage process: (1) Fixation of attention; (2) depotentiating habitual frameworks; (3) unconscious search; (4) unconscious processes; (5) therapeutic response.

The *utilization approach* and the *indirect forms of suggestion* are the two major means of facilitating these overall dynamics of therapeutic trance and suggestion. The utilization approach emphasizes the continual involvement of each patient's unique repertory of abilities and potentials, while the indirect forms of suggestion are the means by which the therapist facilitates these involvements.

We believe that the induction and maintenance of therapeutic trance provides a special psychological state in which patients can reassociate and reorganize their inner experience so that therapy results from an inner resynthesis of their own behavior.

Ratifying the process of therapeutic change is an integral part of our approach to hypnotherapy. This frequently involves a special effort to help patients recognize and validate their altered state. The therapist must develop special skills in learning to recognize minimal manifestations of altered functioning in sensory-perceptual, emotional, and cognitive processes. Ideomotor and ideosensory signaling are of special use as an index of therapeutic change as well as a means of facilitating an alteration of the patient's belief system.

Exercises

1. New *observational skills* are the first stage in the training of the hypnotherapist. One needs to learn to recognize the momentary variations in another's mentation. These skills can be developed by training oneself to carefully observe the mental states of people in everyday life as well as in the consulting room. There are at least four levels, ranging from the most obvious to the more subtle.

1. Role relations

2. Frames of reference

3. Common everyday trance behaviors

4. Response attentiveness

1. Role relations: Carefully note the degree to which individuals in all walks of life are caught within roles, and the degrees of flexibility they have in breaking out of their roles to relate to you

as a unique person. For example, to what degree are the clerks at the supermarket identified with their roles? Notice the nuances of voice and body posture that indicate their role behavior. Does their tone and manner imply that they think of themselves as an authority to manipulate you, or are they seeking to find out something about you and what you really need? Explore the same questions with police, officials of all sorts, nurses, bus drivers, teachers, etc.

2. Frames of reference: To the above study of 'role relations add an inquiry into the dominant frames of reference that are guiding your subject's behavior. Is the bus or taxicab driver more dominated by a safety fame of reference? Which of the store clerks is more concerned with securing his present job and which is obviously bucking for a promotion? Is the doctor more obviously operating within a financial or therapeutic frame of reference?

3. Common everyday trance behavior: Table 1 can be a guide as to what to look for in evaluating a person's everyday trance behavior. Even in ordinary conversation one can take careful note of those momentary pauses when the other person is quietly looking off into the distance or staring at something, as he or she apparently reflects inward. One can ignore and actually ruin these precious moments when the other is engaged in inner search and unconscious processes by talking too much and thereby distracting the person. How much better simply to remain quiet oneself and carefully observe the individual manifestations of the other's everyday trance behavior. Notice especially whether the person's eye blink slows down or stops altogether. Do the eyes actually close for a moment? Does the body not remain perfectly immobile, perhaps even with limbs apparently cataleptic, fixed in mid-gesture?

Watching for these moments and pauses is especially important in psychotherapy. The authors will themselves sometimes freeze in mid-sentence when they observe the patient going off into such inward focus. We feel what we are saying is probably less important than allowing the patient to have that inward moment. Sometimes we can facilitate the inner search by simply saying things such as:

That's right, continue just as you are.

Follow that now.

Interesting isn't it?

Perhaps you can tell me some of that later.

After a while patients become accustomed to this unusual tolerance and reinforcement of their inner moments; the pauses grow longer and become what we would call therapeutic trance. The patients then experience increasing relaxation and comfort and may prefer to respond with ideomotor signals as they give increasing recognition to their trance state.

4. Response Attentiveness: This is the most interesting and useful of the trance indicators. The junior author can recall that lucky day when a series of three patients seen individually on successive hours just happened to manifest a similar wide-eyed look of expectancy, staring fixedly

into his eyes. They also had a similar funny little smile (or giggle) of wistfulness and mild confusion. That was it! Suddenly he recognized what the senior author had been trying to teach him for the past five years: Response attentiveness! The patients may not have realized themselves just how much they were looking to the junior author for direction at that moment. That was the moment to introduce a therapeutic suggestion or frame of reference! That was the moment to introduce trance either directly or indirectly! The junior author can recall the same slight feeling of discomfort with each patient at that moment. The patient's naked look of expectancy bespoke a kind of openness and vulnerability that is surprising and a bit disconcerting when it is suddenly encountered. In everyday situations we tend to look away and distract ourselves from such delicate moments. At most we allow ourselves to enjoy them briefly with children or during loving encounters. In therapy such creative moments are the precious openers of the yes set and positive transference. Hypnotherapists allow themselves to be open to these moments and perhaps to be equally vulnerable as they offer some tentative therapeutic suggestions. More detailed exercises on the recognition and utilization of response attentiveness will be presented at the end of Chapter Three.

CHAPTER 2

The Indirect Forms of Suggestion

1. Direct and Indirect Suggestion

A direct suggestion makes an appeal to the conscious mind and succeeds in initiating behavior when we are in agreement with the suggestion and have the capacity actually to carry it out in a voluntary manner. If someone suggests, Please close the window, I will close it if I have the physical capacity to do so, and if I agree that it's a good suggestion. If the conscious mind had a similar capacity to carry out all manner of psychological suggestions in an agreeable and voluntary manner, then psychotherapy would be a simple matter indeed. The therapist would need only suggest that the patient give up such and such a phobia or unhappiness and that would be the end of the matter.

Obviously this does not happen. Psychological problems exist precisely because the conscious mind does not know how to initiate psychological experience and behavior change to the degree that one would like. In many such situations there is some capacity for desired patterns of behavior, but they can only be carried out with the help of an unconscious process that takes place on an involuntary level. We can make a conscious effort to remember a forgotten name, for example, but if we cannot do so, we cease trying after a few moments of futile effort. Five minutes later the name may pop up spontaneously within our minds. What has happened? Obviously a search was initiated on a conscious level, but it could only be completed by an unconscious process that continued on its own even after consciousness abandoned its effort. Sternberg (1975) has reviewed experimental data supporting the view that an unconscious search continues at the rate of approximately thirty items per second even after the conscious mind has gone on to other matters.

The indirect forms of suggestion are approaches to initiating and facilitating such searches on an unconscious level. When it is found that consciousness is unable to carry out a direct suggestion, we may then make a therapeutic effort to initiate an unconscious search for a solution by indirect suggestion. The naive view of direct suggestion which emphasizes control maintains that the patient passively does whatever the therapist asks. In our use of indirect suggestion, however, we realize that suggested behavior is actually a subjective response synthesized within the patient. It is a subjective response that utilizes the patient's unique repertory of life experiences and learning. It is not what the therapist says but what the patient does with what is said that is the essence of suggestion. In hypnotherapy the words of the therapist evoke a complex series of internal responses within the patient; these internal responses are the basis of suggestion. Indirect suggestion does not tell the patient what to do; rather, it explores and facilitates what the patient's response system can do on an autonomous level without really making a conscious effort to direct itself.

The indirect forms of suggestion are semantic environments that facilitate the experience of new response possibilities. They automatically evoke unconscious searches and processes within us independent of our conscious will.

In this chapter we shall discuss a number of indirect forms of suggestion that have been found to be of practical value in facilitating hypnotic responsiveness. Most of these indirect forms are in common usage in everyday life. Indeed, this is where the senior author usually recognized their value as he sought more effective means of facilitating hypnotic work.

Because we have already discussed most of these indirect forms from a theoretical point of view (Erickson and Rossi, 1976; Erickson, Rossi, and Rossi, 1976), our emphasis in this chapter will be on their therapeutic applications. It will be seen that many of these indirect forms are closely related to each other, that several can be used in the same phrase or sentence, and that it is sometimes difficult to distinguish one from another. Because of this, it may be of value for the reader to recognize that an attitude or approach is being presented with this material rather than a" technique" that is designed to achieve definite and predictable (though limited) results. *The indirect forms of suggestion are most useful for exploring potentialities and facilitating a patient's natural response tendencies rather than imposing control over behavior.*

2. The Interspersal Approach

The senior author has described the *interspersal* approach (Erickson, 1966; Erickson and Rossi, 1976) along with *nonrepetition* as his most important contributions to the practice of suggestion [*In a conversation with Anisley Mears, Gordon Ambrose, and others on the evening when the senior author, at the age of seventy-four, was awarded the Benjamin Franklin gold medal for his innovative contributions to hypnosis at the 7th International Congress of Hypnosis on July 2, 1976.*]. In the older, more traditional forms of direct suggestion the hypnotherapist usually droned on and on, repeating the same suggestion over and over. The effort was seemingly directed to programming or deeply imprinting the mind with one fixed idea. With the advent of modern psychodynamic psychology, however, we recognize that the mind is in a continual state of growth and change; creative behavior is in a continual process of development. While direct programming can obviously influence behavior (e.g., Coueism, advertising), it does not help us explore and facilitate a patient's unique potentials. The interspersal approach, on the other hand, is a suitable means of presenting suggestions in a manner that enables the patient's own unconscious to utilize them in its own unique way.

The interspersal approach can operate on many levels. We can within a single sentence intersperse a single word that facilitates the patient's associations:

You can describe those feelings *as freely as* you wish.

The interspersed word *freely* automatically associates a positive valence of freedom with feelings patients may have suppressed. It can thereby help patients to free feelings that they really want to reveal. Each patient's individuality is still respected, however, because free choice is admitted. The senior author (Erickson, 1966) has illustrated how an entire therapeutic session can be conducted

by interspersing words and concepts suggestive of comfort, utilizing the patient's own frames of reference so that pain relief is achieved without the formal induction of trance. Case 1 of this volume will give another clear illustration of this approach. In the following sections we will discuss and illustrate *indirect associative focusing* and *indirect ideodynamic focusing* as two aspects of the interspersal approach.

2a. Indirect Associative Focusing

A basic form of indirect suggestion is to raise a relevant topic without directing it in any obvious manner to the patient. The senior author likes to point out that the easiest way to help patients talk about their mothers is to talk about your own mother or mothers in general. A natural indirect associative process is thereby set in motion within patients that brings up apparently spontaneous associations about their mothers. Since we do not directly ask about a patient's mother, the usual limitations of conscious sets and habitual mental frameworks (including psychological defenses) that such a direct question might evoke are bypassed. Bandler and Grinder (1975) have described this process as a transderivational phenomenon - a basic linguistic process whereby subject and object are automatically interchanged at a deep, (unconscious), structural level.

In therapy we can use a process of indirect associative focusing to help a patient recognize a problem. The senior author, for example, will frequently intersperse remarks or tell a number of stories and anecdotes in seemingly casual conversation. Even when his stories appear unrelated, however, they all have a common denominator or common focused association which he hypothesizes to be a relevant aspect of the patient's problem. Patients may wonder why the therapist is making such interesting but apparently nonrelevant conversation during the therapy hour. If the common, focused association is in fact a relevant aspect of their problem, however, patients will frequently find themselves talking about it in a surprisingly revelatory manner. If the therapist guessed wrong, nothing is lost. The patient will simply not talk about the focused association because there is no particular recognition and contribution within the patient's own associative processes to raise it to the verbal level.

A major value of this interspersal approach is that therapists can to some degree avoid imposing their own theoretical views and preoccupations upon their patients. If the focused association is of value to patients, their own unconscious processes of search and evaluation will permit them to recognize it as an aspect of their problem and utilize it in their own way to find their own solutions. Examples of this process of indirect associative focusing to help patients recognize and resolve psychodynamic problems will be presented in a number of case illustrations of this volume (e.g., particularly Case 5, a general approach to symptomatic behavior).

2b. Indirect Ideodynamic Focusing

One of the earliest theories of hypnotic responsiveness was formulated by Bernheim (1895), who described it as *a peculiar aptitude for transforming the idea received into an act.* He believed, for example, that in the hypnotic experience of catalepsy there was ' *'an exaltation of the idea-motor*

reflex excitability, which effects the unconscious transformation of the thought into movement, unknown to the will. In the hypnotic experience of sensory hallucinations he theorized that the *memory of sensation [is]* resuscitated along with *exultation of the ideo-sensorial reflex excitability, which effects the unconscious transformation of the thought into sensation, or into a sensory image."* This view of ideodynamic responsiveness (that ideas can be transformed into an actual experience of movements, sensations, perceptions, emotions, and so on, independently of conscious intentionality) is still tenable today. Our utilization theory of hypnotic suggestion emphasizes that suggestion is a process of evoking and *utilizing* a patient's own mental processes in ways that are outside his usual range of ego control (Erickson and Rossi, 1976).

Ideodynamic processes can be evoked with an interspersal approach utilizing indirect associative focusing as described in the previous section. When the senior author addressed professional groups about hypnotic phenomena, for example, he frequently interspersed interesting case histories and told stories about hand levitation or hallucinatory sensations. These vivid illustrations initiated a natural process of ideomotor and ideosensory responsiveness within the listeners without their being aware of it. When he then asked for volunteers from the audience for a demonstration of hypnotic behavior, they were primed for responsiveness by ideodynamic processes that were already taking place within them in an involuntary manner on an unconscious level. These unrecognized ideodynamic responses can frequently be measured by electronic instrumentation (Prokasy and Raskin, 1973).

In a similar manner, when confronted with a resistant subject we can surround him with one or more good hypnotic subjects to whom we direct our hypnotic suggestions. A process of indirect ideodynamic responsiveness takes place automatically within the resistant subject as he listens to the suggestions and observes the responses of others. He is soon surprised at how the hypnotic atmosphere effects him so that he becomes much more responsive than before.

Many clear illustrations of this process of interspersing indirect ideodynamic suggestion will be found in the cases of this book. In our first case, for example, the senior author talks about his friend John, who had phantom limb pain in his foot just like the patient's: John was marvelous. And I discussed with him the importance of having nice feelings in your wooden foot, your wooden knee. . . . The importance of having good feelings in the wooden foot, the wooden knee, the wooden leg. Feeling it to be warm. Cool. Rested . . . you can have phantom pleasure.

In the context of a number of anecdotes and stories about how others have learned to experience phantom pleasure instead of pain, interspersed indirect ideodynamic suggestions such as the above begin automatically to initiate unconscious searches and processes that will lead to the amelioration of phantom pain even without the formal induction of trance.

3. Truisms Utilizing Ideodynamic Processes

The basic unit of ideodynamic focusing is the truism: a simple statement of fact about behavior that the patient has experienced so often that it cannot be denied. In most of our case illustrations it will be found that the senior author frequently talks about certain psychophysiological processes

or mental mechanisms as if he were simply describing objective facts to the patient. Actually these verbal descriptions can function as indirect suggestions when they trip off ideodynamic responses from associations and learned patterns that already exist within patients as a repository of their life experience. The generalized reality orientation (Shor, 1959) usually maintains these subjective responses in appropriate check when we are engaged in ordinary conversation. When attention is fixed and focused in trance so that some of the limitations of the patient's habitual mental sets are depotentiated, however, the following truisms may actually trip off a literal and concrete experience of the suggested behavior, which is printed in *italics.*

3a. Ideomotor Processes

Most people can experience *one hand as being lighter than another.*

Everyone has had the experience *of nodding their head yes or shaking it no even without realizing it.*

When we are *tired, our eyes begin to blink slowly and sometimes close* without our quite realizing it.

Sometimes as we relax or go to sleep, a muscle will twitch so that *our arm or leg makes a slight involuntary movement* (Overlade, 1976).

3b. Ideosensory Processes

You already know how to experience pleasant sensations like the *warmth* of the sun *on your skin.*

Most people enjoy the *refreshing coolness* of a light breeze.

Some people can imagine their favorite food so well they can actually *taste* it.

The salt and *smell* of a light ocean breeze is pleasant to most people.

3c. Ideoaffective Processes

Some people *blush easily when they recognize certain feelings* about themselves.

Its easy *to feel anger and resentment* when we are made to feel foolish. We usually *frownwhen we have memories that are all too painful to*

remember.

Most of us try to avoid *thoughts and memories that bring tears,* yet they frequently deal with the most important things.

We have all enjoyed noticing someone *smile at a private thought* and we frequently find ourselves *smiling at their smile.*

In formulating such ideoaffective suggestions it is helpful to include a behavioral marker (blush, frown, tears, smile) whenever possible, to provide some possible feedback to the therapist about what the patient is receiving and acting upon.

3d. Ideocognitive Processes

We know that when you are asleep your unconscious can *dream*. You can *easily forget* that dream when you awaken.

You can sometimes *remember*one important part of that dream that interests you.

We can sometimes know a name and have it on the tip of our tongue and yet *not be able to say* the name.

4. Truisms Utilizing Time

In hypnotherapeutic work truisms utilizing time are very important because there is frequently a time lag in the execution of hypnotic responses. The stages of unconscious search and processes leading to hypnotic responses require varying lengths of time in different patients. It is usually best to permit the patient's own unconscious to determine the appropriate amount of time required for any response.

***Sooner or later* your hand is going to lift (eyes close, or whatever).**

Your headache (or whatever) can *now* leave *as soon as* your system is ready for it to leave.

Your symptom can *now* disappear*as soon as* your unconscious knows you can handle (such and such) problem in a more constructive manner.

5. Not Knowing, Not Doing

While truisms are an excellent means of introducing suggestions in a positive manner that the conscious mind can accept, valid hypnotic experience involves the utilization of unconscious processes. A basic aspect of therapeutic trance is to arrange circumstances so that constructive mental processes are experienced in taking place by themselves without the patient making any effort to drive or direct them. When one is relaxed, as is typical of most trance experiences, the parasympathetic system physiologically predisposes one *not to do* rather than to make any active effort of doing. Similarly when we are relaxed and the unconscious takes over, we usually feel comfortable and *do not know* how the unconscious carries out its activities. Not knowing and not doing are synonymous with the unconscious or autonomous responsiveness that is the essence of

trance experience. An attitude of not knowing and not doing is therefore of great value in facilitating hypnotic responsiveness. This is particularly true during the initial stages of trance induction, where the following suggestions may be appropriate.

You don't have to talk or move or make any sort of effort. You don't even have to hold your eyes open.

You don't have to bother trying to listen to me because your unconscious can do that and respond all by itself.

People can sleep and not know they are asleep.

They can dream and not remember that dream.

You don't know just when those eyelids will close all by themselves.

You may not know just which hand will lift first.

These examples clearly illustrate how different our indirect hypnotic forms are from the direct approach, which typically begins, Now pay close attention to my voice and do exactly what I say. The direct approach focuses conscious attention and tends to activate conscious cooperation by the patient. This can be of value in initiating some types of responsive behavior in good hypnotic subjects, but for the average patient it may activate conscious processes to the point where unconscious processes are inhibited rather than enhanced.

Not knowing and not doing are of particular value in trance work when we wish to evoke the patient's own individuality in seeking the best modality of therapeutic response.

You don't really know just how your unconscious will help you resolve that problem. But your conscious mind can be receptive to the answer when it does come.

Your conscious mind surely has many questions, but it does not really know just when the unconscious will let you give up that undesirable habit. You don't know if it will be sooner or later. You don't know if it will be all at once or slowly, by degrees. Yet you can learn to respect your own natural way of doing things.

6. Open-Ended Suggestions

Therapists as well as patients do not always know what is the best avenue for constructive processes to express themselves. Human predispositions and potentialities are so complex that we may even consider it presumptuous to assume that anyone could possibly know ahead of time just what is the most creative approach to the new that continually overtakes us. Indeed, one view of maladjustment is that we do in fact attempt to impose old views and solutions into changed life circumstances where they are no longer appropriate (Rossi, 1972). The open-ended suggestion is

a means of dealing with this problem. Open-ended suggestions permit us to explore and utilize whatever response possibilities are most available to the patient. It is of value on the level of conscious choice as well as unconscious determinism. When patients are awake and consciously directing their own behavior, the open-ended suggestion permits self-determination. When patients are in trance, the open-ended suggestion permits the unconscious to select the most appropriate means of carrying out a therapeutic response.

As we have already seen, not knowing and not doing lead naturally to open-ended suggestions. The following are further illustrations.

We all have potentials we are unaware of, and we usually don't know how they will be expressed.

Your mind can review more feelings, memories, and thoughts related to that problem, but you don't know yet which will be most useful for solving the problem you are coping with.

You can find yourself ranging into the past, the present, or the future as your unconscious selects the most appropriate means of dealing with that.

He doesn't know what he is learning, but he is learning. And it isn't right for me to tell him, You learn this or you learn that! Let him learn whatever he wishes, in whatever order he wishes.

While giving a great deal of apparent freedom to explore and express the patient's own individuality, such open-ended suggestions carry a strong implication that a therapeutic response will be forthcoming.

7. Covering All Possibilities of a Class of Responses

While open-ended suggestions permit the widest possible latitude for the expression of a therapeutic response, suggestions covering all possibilities of a class of responses are of more value when the therapist wishes to focus the patient's responsiveness in a particular direction. In initiating trance, for example, the following might be appropriate.

Soon you will find a finger or a thumb moving a bit, perhaps by itself. It can move up or down, to the side or press down. It can be slow or quick or perhaps not move at all. *The really important thing is to sense fully whatever feelings develop.*

All possibilities of finger movement have been covered, including the possibility of not moving at all. The suggestion is thus fail-safe. The patient is successful no matter what response develops. The therapist is simply exploring the patient's initial responsiveness while initiating trance by focusing attention.

Exactly the same approach can be used when the patient has experienced therapeutic trance and is

ready to deal with a problem.

Soon you will find the weight problem being dealt with by eating more or less of the right foods you can enjoy. You may first gain weight or lose it or remain the same for a while *as you learn the really important things about yourself.*

In both of these illustrations we can observe how we are distracting the patient's consciousness from the important area of responsiveness with an interesting idea in the end (in *italics),* so that the unconscious can have more opportunity to determine which of the response possibilities (not in italics) will be expressed. This is in keeping with the classical notion of hypnosis as the simultaneous focusing and distraction of attention.

8. Questions That Facilitate New Response Possibilities

Recent research (Steinberg, 1975) indicates that the human brain, when questioned, continues an exhaustive search throughout its entire memory system on an unconscious level even after it has found an answer that is apparently satisfying on a conscious level. This unconscious search and activation of mental processes on an autonomous level is the essence of our indirect approach, wherein we seek to utilize a patient's unrecognized potentials to evoke hypnotic phenomena and therapeutic responses.

This process of an unconscious search and an autonomous processing of information is evident in many phenomena of everyday life. According to one folk saying, The morning is wiser than the evening. After we have slept on a problem, we find the solution comes more easily in the morning. Evidently an unconscious search and problem-solving process has been taking place while the consciousness was at rest. There is evidence that dreaming can be an experimental theater of the mind, where questions can be answered and new life possibilities synthesized (Ross, 1971-1973).

The Socratic method of education, whereby a teacher asks the student a series of pointed questions, is a classical illustration of using questions as initiators of mental processes. We can wonder, indeed, if consciousness could have evolved to its current level without the development and utilization of questions as a provocative syntactical form which facilitate internal processes of inquiry. In this section we will illustrate how questions can focus associations as well as suggest and reinforce new response possibilities.

8a. Questions to Focus Associations

An interesting illustration of how questions can focus different aspects of inner experience comes from research on the subjective reports of hypnotic subjects (Barber, Dalai, and Calverley, 1968). When asked, Did you experience the hypnotic state as basically *similar* to the waking state? most subjects (83 percent) reported affirmatively. On the other hand, when asked, Did you experience the hypnotic state as basically *different* from the waking state? 72 percent responded affirmatively. We could take these apparently contradictory responses as indications of the unreliability of the subjects' reports about the hypnotic experience. From another point of view,

however, we can understand how such questions focused the subjects on different aspects of their experiences. The first question focused their attention on the similarities between the waking and hypnotic states; the second focused attention on the differences. Both questions could initiate valid responses about different aspects of the subjects' inner experiences; no contradiction need be implied.

In hypnotherapy it is often of value to help patients discriminate between different aspects of their inner lives or to find the common denominator in apparently different experiences. Carefully formulated questions such as the above can facilitate this process.

8b. Questions in Trance Induction

Questions are of particular value as indirect forms of suggestion when they cannot be answered by the conscious mind. Such questions activate unconscious processes and initiate autonomous responses which are the essence of trance behavior. The following are illustrations of how a series of questions may be used to initiate and deepen trance by two different approaches to induction - eye fixation and hand levitation. In each illustration the first few questions may be answered by responsive behavior that is guided by conscious choice. The next few questions may be answered by either conscious intentionality or unconscious choice. The last few can only be answered on an unconscious or autonomous level of responsiveness. These series of questions cannot be used in a fixed and rigid manner, but must always incorporate and utilize the patient's ongoing behavior. It is understood that patients need not respond in a conventional verbal manner to these questions, but only with the responsive behavior suggested. Patients usually do not recognize that a very important but subtle shift is taking place. They are no longer verbally interacting in a social manner with their typical defenses. Rather, they are focused intensely within themselves wondering about how they will respond. This implies that a dissociation is taking place between their conscious thinking (with its sense of control) and their apparently autonomous responses to the therapist's questions. The apparently autonomous nature of their behavioral responses is usually acknowledged as hypnotic . With that the stage is set for further autonomous and unconsciously determined therapeutic responses.

Eye Fixation

1. **1. Would you like to find a spot you can look at comfortably?**

2. **2. As you continue looking at that spot for a while, do your eyelids want to blink?**

3. **3. Will those lids begin to blink together or separately?**

4. **4. Slowly or quickly?**

5. **5. Will they close all at once or flutter all by themselves first?**

6. **6. Will those eyes close more and more as you get more and more comfortable?**

7. **7. That's fine. Can those eyes now remain closed as your comfort deepens like when you go to sleep?**

8. **8. Can that comfort continue more and more so that you'd rather not even try to open your eyes?**

9. **9. Or would you rather try and find you cannot?**

10. **10. And how soon will you forget about them altogether because your unconscious wants to dream? (Therapist can observe slight eyeball movements as the patient's closed eyes follow changes on the inner dream scene.)**

This series begins with a question that requires conscious choice and volition on the part of the patient and ends with a question that can only be carried out by unconscious processes. An important feature of this approach is that it *is fail-safe* in the sense that any failure to respond can be accepted as a valid and meaningful response to a question. Another important feature is that each question suggests an *observable* response that gives the therapist important information about how well the patient is following suggestions. These observable responses are also associated with important internal aspects of trance experience and can be used as *indicators* of them.

If there is a failure to respond adequately, the therapist can go on with a few other questions at the same level until responsive behavior is again manifest, or the therapist can question patients about their inner experience to explore any unusual response patterns or difficulties they may have. It is not uncommon for some patients, for example, to open their eyes occasionally even after it is suggested that they will remain closed. This seems to be an automatic checking device that some patients use without even being aware of it. It does not interfere with therapeutic trance work. The question format thus gives each patient's own *individuality* an opportunity to respond in a therapeutically constructive manner. These features are also found in the hand-levitation approach, which we will now illustrate.

Hand Levitation

1. **1. Can you feel comfortable resting your hands gently on your thighs? [As therapist demonstrates] That's right, without letting them touch each other.**

2. **2. Can you let those hands rest ever so lightly so that the fingertips just barely touch your thighs?**

3. **3. That's right. As they rest ever so light, do you notice how they tend to lift up a bit all by themselves with each breath you take?**

4. **4. Do they begin to lift even more lightly and easily by themselves as the rest of your body relaxes more and more?**

5. **5. As that goes on, does one hand or the other or maybe both continue lifting even more?**

6. **6. And does that hand stay up and continue lifting higher and higher, bit by bit, all by itself? Does the other hand want to catch up with it, or will the other hand relax in your lap?**

7. **7. That's right. And does that hand continue lifting with these slight little jerking movements, or does the lifting get smoother and smoother as the hand continues upward toward your face?**

8. **8. Does it move more quickly or slowly as it approaches your face with deepening comfort? Does it need to pause a bit before it finally touches your face so you'll know you are going into a trance? And it won't touch until your unconscious is really ready to let you go deeper, will it?**

9. **9. And will your body automatically take a deeper breath when that hand touches your face as you really relax and experience yourself going deeper?**

10. **10. That's right. And will you even bother to notice the deepening comfortable feeling when that hand slowly returns to your lap all by itself? And will your unconscious be in a dream by the time that hand comes to rest?**

8c. Questions Facilitating Therapeutic Responsiveness

Questions can be combined with not knowing and with open-ended suggestions to facilitate a variety of patterns of responsiveness.

And what will be the effective means of losing weight? Will it be because you simply forget to eat and have little patience with heavy meals because they prevent you from doing more interesting things? Will certain foods that put on weight no longer appeal to you for whatever reasons? Will you discover the enjoyment of new foods and new ways of preparing them and eating so that you'll be surprised that you did lose weight because you really didn't miss anything?

The last question in this series is an illustration of how compound questions can be built up with *and* and *so* to facilitate whatever tendency is most natural for the patient.

The ambiguity and suggestive effect of compound questions has long been recognized in jurisprudence. The use of compound questions by attorneys is therefore forbidden during their cross-examination of a witness. In a hotly contested case a judge or an opposing attorney can often be heard objecting to the compounds by which an unscrupulous attorney may befuddle and perhaps ensnare an unwary witness. In our therapeutic use of compound questions their very ambiguity is of value in depotentiating the patient's learned limitations so new possibilities may be experienced.

We will now turn to a more detailed examination of compound suggestions.

9. Compound Suggestions

We have already seen in many of our previous illustrations how two or more suggestions can be combined to support each other. In this section we shall take a closer look at a variety of compound suggestions that have been found to be of value in hypnotherapeutic work. At the simplest level a compound suggestion is made up of two statements joined together with a grammatical conjunction or with a slight pause that places them in close association. Traditional grammar has classified conjunctions broadly *as coordinating and subordinating.* The coordinating conjunctions *and, but,* and *or* join statements that are logically coordinated or equal in rank, while subordinating conjunctions such as *though, if, so, as, after, because, since,* and *until* join one expression to another that is its adjunct or subordinate. The linguistic joining and separating expressions obviously have correspondences with similar processes in mathematics and logic as well as with the psychological processes of mental association and dissociation that are of essence in hypnotherapy. George Boole (1815-1864), one of the originators of symbolic logic, felt that he was formulating the laws of thought with his equations. We know today, however, that while logic, natural language, and mental processes share some intriguing interfaces, there is no system of complete correspondence between them. While a system of logic or mathematics can be completely defined, *natural language and mental processes are perpetually in a state of creative flux.* There is in principle no fixed formula or system of logic or language that can completely determine or control mental processes. We would be deluding ourselves, therefore, if we sought a completely deterministic means of manipulating mental processes and controlling behavior with our indirect forms of suggestion. We can use them to explore and facilitate response potentials within the patient, however. In this section we will illustrate five classes of compound suggestion that have been of particular use in hypnotherapy: (a) the yes set and reinforcement, (b) contingency, (c) apposition of opposites, (d) the negative, and (e) shock, surprise, and creative moments. Other forms of indirect suggestion such as implication, binds, and double binds are so complex that we will discuss them in separate sections.

9a. The Yes Set and Reinforcement

A basic form of compound statement widely used in daily life is the simple association of a certain and obviously good notion with the suggestion of a desirable possibility.

It's such a beautiful day, let's go swimming.

It's a holiday, *so* why shouldn't I do what I want?

You have done well *and* can continue.

In each of the above an initially positive association (beautiful day, holiday, done well) introduces a yes set that facilitates the acceptance of the suggestion that follows. We saw earlier how truisms are another means of opening a yes set to facilitate suggestion.

When the truism or positive and motivating association *follows* the suggestion, we have a means of reinforcing it. Thus:

Let's go swimming, it's such a beautiful day.

9b. Contingent Suggestions and Associational Networks

A useful form of compound statement occurs when we tie a suggestion to an ongoing or inevitable pattern of behavior. A hypnotic suggestion that may be difficult for a patient is easier when it is associated with behavior that is familiar. The hypnotic suggestion hitchhikes onto the natural and spontaneous responses that are well within the patient's normal repertory. The contingent suggestion is *italicized*in the following examples.

With each breath you *take you can become aware of the natural rhythms of your body and feelings of comfort that develop.*

As you continue sitting *there, you will find yourself becoming more relaxed and comfortable.*

As your hand *lowers, you'll find yourself going comfortably back in time to the source of that problem.*

As you mentally review the source of that *problem your unconscious can develop some tentative ways of dealing with it.*

And when your conscious mind recognizes a plausible and worthwhile *solution, your finger can lift automatically.*

When you feel ready to talk about *it, you'll find yourself awakening feeling refreshed and alert, with an appreciation of the good work you've been able to do.*

As can be seen from the last four examples, contingent suggestions can be tied together into associational networks that create a system of mutual support and momentum for initiating and carrying out a therapeutic pattern of responses. From the broadest point of view a whole therapy session - indeed, an entire course of therapy - can be conceived as a series of contingent responses wherein each successful therapeutic step evolves from all that came before. Haley (1974) has presented a number of the senior author's clinical cases that illustrate this process.

9c. Apposition of Opposites

Another indirect form of compound suggestion is what we may describe as the balance or apposition of opposites. A balance between opponent systems is a basic biological process that is built into the structure of our nervous system (Kinsbourne, 1974). Most biological systems can be conceptualized as a homeostatic balance of processes that prevents the overall system from straying outside the relatively narrow range required for optimal functioning. To account for some of the phenomena of hypnosis, it has been proposed that there are alternatives in various opponent

systems, such as the sympathetic and parasympathetic system, the left and right cerebral hemispheres, cortical versus subcortical processes, the first and second signaling system (Platonov, 1959).

This balancing or apposition of opponent processes is also evident on the psychological and social levels. There is tension and relaxation, motivation and inhibition, conscious and unconscious, eros and logos, thesis and antithesis. An awareness and understanding of the dynamics of such opponent processes is of greatest significance in any form of psychotherapy. In this section we can provide only a few illustrations of how we can balance opponent processes by means of verbal suggestion. In the process of hypnotic induction, for example, we have the following:

As that fist gets tighter and *tense,* the rest of your body *relaxes.* As your right hand *lifts,* your left hand *lowers.*

As that *arm feels lighter* and lifts, your eyelids can feel *heavier* and *lower* until they are closed.

Similar suggestions can be formulated for virtually any of the opponent processes in the sensory, perceptual, affective, and cognitive realms.

As your forehead gets *cooler,*your hands can get *warmer.*

As your jaw becomes more and more *numb and insensitive,* notice how your left hand becomes more and more *sensitive.*

You can *experience* all your feelings about something that occurred at age X without being able to *remember*just what caused those feelings.

When you next open your eyes you will have an unusually clear *memory* of all that, but without *the feelings* you had then.

As you review that, you can now experience an appropriate balance of *thinking and feeling* about the whole thing.

As can be seen from the last three examples, a process of dissociation can be utilized to first help the patient very thoroughly experience both sides of an opponent system before they are brought together at a more adequate level of integration.

9d. The Negative

Closely associated with the apposition of opposites is the senior author's emphasis on the importance of discharging the negativity or resistance that builds up whenever a patient is following a series of suggestions. In everyday life we can recognize how people who are negative or resistant usually have a history of feeling they were imposed upon too much. Because of this they now want to have it their way! They resist being overdirected and very often do the opposite

of what they believe others want them to do. This oppositional tendency, of course, is actually a healthy compensation for their early histories. Nature apparently wants us to be individuals, and many believe that the history of man's cultural and psychological development has been an effort to achieve ever-more-encompassing degrees of free, unfettered, and genuine self-expression.

In experimental research psychologists have developed the concept of reactive inhibition to account for similar behavioral phenomena (Woodworth and Schlosberg, 1954). After repeating some task (running a maze, solving certain problems of a similar nature) the subject, whether rat or man, appears less and less willing to go on, and more easily accepts alternative pathways and other patterns of behavior. This inhibition apparently has an adaptive function in blocking previous behavior in favor of the expression of new responses that can lead to new possibilities.

In his practical work with patients, the senior author has explored various means of coping with and actually utilizing this inhibitory or oppositional tendency. He believes that the simple expression of a negative by the therapist can often serve as a lightning rod to automatically discharge any minor inhibition and resistance that has been building up within the patient. Thus he will use such phrases as the following:

And you can, can you *not?* You can try, *can't* you? You *can't* stop it, can you? You will, *won't* you? You do, *don't* you? Why *not* let that happen?

Research has demonstrated another value in this close juxtaposition of the positive and the negative. It has been found that it is 30 percent more difficult to comprehend a negative than a positive (Donaldson, 1959). Thus the use of negatives can introduce confusion that tends to depotentiate a patient's limited conscious set so that inner work can be done.

The use of the negative is also related to another indirect form - not knowing and not doing. This use of the negative can be very usefully and casually introduced in contingent suggestions, such as the following that utilize the connective until.

You*don't* have to go into trance *until* you are really ready.

You*won't* take a really deep breath *until* that hand touches your face.

You*won't* really know just how comfortable you can be in trance *until* that arm slowly lowers all the way down to rest on your lap.

And you really *don't* have to do [therapeutic response] *until* [Inevitable behavior in patient's near future].

You*won't* do it until your unconscious is ready.

The latter use of the negative is actually a form of the conscious-unconscious double bind we will discuss in a later section.

9e. Shock, Surprise, and Creative Moments

A most interesting form of compound suggestion is illustrated when a shock surprises patients' habitual mental frameworks so their usual conscious sets are depotentiated and there is a momentary gap in their awareness, which can then be filled with an appropriate suggestion (Rossi, 1973; Erickson and Rossi, 1976). The shock opens the possibility of a creative moment during which the patient's unconscious is engaged in an inner search for an answer or conception that can reestablish psychic equilibrium. If the patient's own unconscious processes do not provide the answer, the therapist has an opportunity to introduce a suggestion that may have the same effect.

Shock and surprise can sometimes precipitate autonomic reactions that are normally not under voluntary control. At a delicate moment in a conversation one sometimes blushes in an uncontrolled manner when unconscious emotional processes are touched upon. If a person is not blushing during such an unguarded moment, one can frequently precipitate a blushing response by simply asking, Why are you blushing? This *question* - as an indirect form of suggestion administered during the delicate (potentially creative) moment when the listener's habitual mental frameworks are in nascent flux - evokes the suggested autonomic processes easily.

In everyday life a loud noise may startle us so that we freeze, momentarily inhibiting all body movement; we are thrown into a momentary trance as the unconscious races for a means of comprehending what is happening. The answer may flash that it was only a car backfiring, and we relax. But if in that precise moment someone yells the suggestion, bomb! we almost certainly will flinch, look around in panic, or fall to the ground to protect ourselves. Daily life is filled with less dramatic examples of unexpected shocks that startle and surprise and perhaps lead to a double-take, where we have to look back or go over that again to comprehend what is really going on. We could theorize that foul language is actually a form of shock that has developed in most cultures to startle the listeners so they will be more available to what is being said and be more readily influenced by it.

If people have problems because of learned limitations, it can be therapeutic to momentarily depotentiate those limitations with some form of psychological shock. They can then reevaluate their situation via the automatic process of unconscious search that is initiated within them. In this case the process of shock, surprise, and creative moments is open-ended; the patient's own unconscious processes provide whatever reorganization or solution that emerges. If nothing satisfactory comes forth, the therapist may then add suggestions as further stimuli during the momentary gap, in hope that they may catalyze a therapeutic response.

Momentary shock can be generated in therapeutic dialogue by *interspersing* shock words, taboo concepts, and emotions. Words like *sex, secrets,* and *whispering* momentarily fix attention, and the listener is more receptive. A momentary pause after the shock allows an inner search to take place. It can be followed by reassurance or an appropriate suggestion.

Yours*ex* life

[Pause]

just what you need to know and understand about it.

***Secretly* what you want**

[Pause]

is most important to you.

You may get *divorced*

[Pause]

unless you both really learn to get what you need in the relationship.

In each of these examples the shock in italics initiates an inner search that can lead to the expression of an important response during the pause. The therapist learns to recognize and evaluate the nonverbal body reactions to such psychological shock. If there are indications that the patient has become preoccupied with the inner search, the therapist simply remains quiet until the patient comes forth with whatever material has been stimulated. If there are no indications of material coming from the patient, the therapist ends the pause with a reassurance or suggestion, as illustrated above. The most effective initiators of shock utilize the patient's own frames of reference, taboos, and needs for a break out of the old so that a creative reorganization can take place. Illustrations of this process have been published elsewhere (Rossi, 1973b), and detailed clinical examples will be found in a number of the cases in this volume.

10. Implication and the Implied Directive

Implication is a basic linguistic-psychological form that provides us with the clearest model of the dynamics of indirect suggestion. Most psychotherapists agree that it is not what the therapist says that is important but what the patient hears. That is, the words of the therapist only function as stimuli that set off many personal trains of association within the patient. It is these personal trains of association within the patient that actually function as a major vehicle for the therapeutic process. This process can be disrupted when the therapist's innocent remarks have unfortunate implications for the patient, but it can be greatly facilitated when the therapist's words carry implications that evoke latent potentials within the patient.

A great deal of communication in daily life as well as in therapy is carried out by implication in a manner that is, for the most part, not consciously planned or even recognized by the participants. We witness this in everyday life when a housewife, for example, bangs her pots a bit louder when she is displeased with her husband but may hum softly to herself when she is pleased. She may not recognize what she is doing, and her husband may not always know quite how he is getting the message, but he feels it at some level. Body language and gesture (Birdwhistell, 1952, 1971; Scheflen, 1974) are nonverbal modes of communication that usually function via implications. In such implication the message is not stated directly but is evoked by a progress of inner search and

inference. This inner search engages the patient's own unconscious processes so that the response that emerges is as much a function of the patient as it is of the therapist. Like all the other indirect forms of suggestion, our psychological use of implication ideally evokes and facilitates the patient's own processes of creativity.

On the simplest level implication is formed verbally by the *If. . . then* phrase.

***If* you sit down *then* you can go into trance.**

Now*if* you uncross your legs and place your hands comfortably on your lap, *then*you will be ready to enter trance.

Patients who follow such suggestions by actually *sitting down, uncrossing their legs,*and *placing their hands in their lap are* also accepting, perhaps without quite realizing it, the implication that they will go into trance.

What is the value of such implication? Ideally such implications bypass consciousness and automatically evoke the desired unconscious processes that will facilitate trance induction in a way that the conscious mind could not because it does not know how. We can prepare ourselves to go to sleep, but the conscious mind cannot make it happen. Thus if we directly order a naive patient, Sit down and go into trance [*The reader will note that even this apparently direct suggestion actually contains an indirect hypnotic form: a compound contingent suggestion where and go into trance is contingent on Sit down . For some particularly apt or experienced subjects, therefore, this statement could facilitate an effective induction.*] he or she may well sit down while politely protesting, But I've never gone into trance, and I'm afraid I don't know how. Since the essence *of hypnotic* suggestion is that responses are carried out on an autonomous or unconscious level, it is usually futile to expect the conscious mind to carry them out via direct suggestion. When direct suggestions are successful, they usually involve preparation for hypnotic work in the same sense that brushing one's teeth and lying in bed are conscious, preparatory acts that set the stage for going to sleep, which is then mediated by unconscious processes. With implication and all the other indirect forms of suggestion, we are presuming to do something more: We are making an effort to evoke and facilitate the actual unconscious processes that will create the desired response.

As we reflect upon the process of implication, we gradually become aware that everything we say has implications. Even the most general conversation can be analyzed as a study in implication - how the words of one speaker can evoke all sorts of associations in the listener. In everyday life as well as in hypnotherapy it is often the *implications that are more potent as suggestions* than what is being said directly. In a public conversation the participants are frequently inhibited, and respond with associations that are nothing more than cliches. In a more personal interaction, such as hypnotherapy, the participants have license to respond with their more intimate or idiosyncratic associations. In such personal interactions we are sometimes ***surprised***at what associations and feelings we experience. When our conscious mind is surprised in this manner, the therapy has been successful in facilitating an expression of our individuality that we were not previously aware of. We could say that potentials have been released or new dimensions of insight and consciousness have been synthesized.

The following are examples of the use of implication for deepening patients' involvement with their own inner realities during trance.

Your own memories, images, and feelings are now more important to you in this state.

While giving an apparently direct suggestion about memories, images, and feelings, this statement also carries the important implication that trance is different from the ordinary awake state, and in this state everything else is irrelevant (outside noises, the time of day, the office setting, etc.).

We are usually not aware of the moment when we fall asleep and sometimes are not even aware that we slept.

This statement has obvious implications for a lack of awareness about the significant aspects of trance, a lack that can further depotentiate the limiting sets of consciousness. This implication is emphasized in the following monologue, which structures a frame of reference in which automatic and unconscious behavior can be facilitated.

Now you know you do many things all day long without being aware of them. Your heart just beats along without any help or conscious direction from you. Just as you usually breathe without being aware of it. And even when you walk, your legs seem to move by themselves and take you wherever you want to go. And your hands do most of the things you want them to do without your saying Now hands do this, now hands do that. Your hands work automatically for you, and you usually don't have to pay attention to them. Even when you speak, you do it automatically, you don't have to be consciously aware of how to pronounce each word. You can speak without even knowing it. You know how to do it automatically without even thinking about it. Also, when you see or hear things or when you touch or feel things, they work automatically without you having to be conscious of them. They work by themselves and you don't have to pay attention. They just take care of themselves without your having to be bothered about them.

10a. The Implied Directive

A special form of implication that is closely associated with contingency suggestions is what we have termed the *implied directive* (Erickson and Rossi, 1976). The implied directive is an indirect form of suggestion that is in common usage in clinical hypnosis (Cheek and LeCron, 1968) even though it has not yet received detailed psychological analysis. Like the other indirect forms of suggestion, its use has evolved out of a recognition of its value in everyday life. The implied directive has three recognizable parts:

1. 1. a time-binding introduction;

2. 2. the implied suggestion that takes place within the patient;

3. 3. behavioral response that signals when the implied suggestion has been accomplished.

Thus, as soon as

1. 1. the time-binding introduction

your unconscious has reached the source of that problem,

2. 2. the implied suggestion initiating an unconscious search taking place within the patient

your finger can lift.

3. 3. the behavioral response that signals when the implied suggestion has been accomplished.

As can be seen from this illustration, the implied directive is an indirect form of suggestion that initiates inner search and unconscious processes and then lets us know when a therapeutic response has been accomplished. It is of particular value when we need to initiate and facilitate an extensive process of inner exploration and when we are attempting to unravel the dynamics of symptom formation.

Other indirect forms of suggestion that are particularly useful for initiating an unconscious search in hypnosis are implied directives such as the following:

When you have found a feeling of relaxation and comfort, your eyes close all by themselves.

In this example the patient must obviously make a search on an unconscious level that will ideally initiate parasympathetic responses that can be experienced as comfort and relaxation. Eye closure is a response naturally associated with such internal comfort and thus serves as an ideal signal that the internal process has taken place.

As that comfort deepens, your conscious mind can relax while your unconscious reviews the nature of the problem. And when a relevant and interesting thought reaches your conscious mind, your *eyes* will open as you carefully consider it.

This example builds upon the first and initiates another unconscious search for a general exploratory approach to a problem.

As can be seen from these examples, an unconscious search initiates an unconscious process that actually solves the problem that the conscious mind could not handle. These unconscious processes are the essence of creativity and problem-solving in everyday life as well as in therapy. Hypnotherapy, in particular, depends upon the successful utilization of such unconscious processes to facilitate a therapeutic response. Cheek and LeCron (1968) have given extensive illustrations of how a series of questions in the form of implied directives can be used for both the exploration and resolution of symptoms.

11. Binds and Double Binds

Pyschological binds and double binds have been explored by a number of authors (Haley, 1963; Watzlawicketal., 1967, 1974;Erickson and Rossi, 1975) for their use in therapeutic situations. The concept of binds appears to have a fascinating potential that extends our quest for new therapeutic approaches into the areas of linguistics, logic, semantics, epistemology, and the philosophy of science. Since they are the vanguard of new patterns of our therapeutic consciousness, our understanding of them is as yet very incomplete. We are not always sure what binds and double binds are, or how we can best formulate and use them. Most of our knowledge about them comes from clinical studies and theoretical formulations (Bateson, 1972) with very little controlled experimental research that exactly specifies their parameters.

Because of this, we will use the terms *bind* and *double bind* only in a very special and limited sense to describe certain forms of suggestion that offer patients an opportunity for therapeutic responses. A *bind* offers a patient a free, conscious choice between two or more alternatives. Whichever choice is made, however, leads the patient in a therapeutic direction. *A double bind,* by contrast, offers possibilities of behavior that are outside the patient's usual range of conscious choice and voluntary control. The double bind arises out of the possibility of communicating on more than one level. In daily life we frequently say something verbally while commenting on it extraverbally. We may say, Let's go to the movies. We can say it with innumerable variations of tone and intent, however, that can have many implications. These variations are all comments or *metacommunications* on our primary verbal message about going to the movies. As we shall see in the following sections, binds and double binds are very much a function of who is receiving the message. What is a bind or double bind for one person may not be for another. As is the case with all the other indirect forms of suggestion, binds and double binds utilize the patient's unique repertory of associations and patterns of long learning. Most binds and double blinds cannot be applied in a mechanical or rote fashion. Therapists must understand something about how their messages are going to be received in order to make it effective.

11a. Binds Modeled on Avoidance-Avoidance and Approach-Approach Conflicts

Psychological binds are life situations in which we experience a constriction in our behavior. Typically we are caught in circumstances that allow us only unpleasant alternatives of response. We are caught between the devil and the deep blue sea. We thus experience an *avoidance-avoidance conflict;* we have to make a choice even though we would like to avoid all the alternatives. In such circumstances we usually choose the lesser of the two evils.

Psychological binds can also be constructed on the model of an *approach-approach conflict.*In this case one is in the bind of having to choose only one of a number of desirable courses of action and excluding all the other desirable possibilities. In common parlance, You can't have your cake and eat it too.

Since we have all had innumerable experiences of such binds, the avoidance-avoidance and approach-approach conflicts usually exist as established processes governing our behavior. As we study patients, we learn to recognize how some are governed more by avoidance-avoidance conflicts while others, perhaps more fortunate (but not necessarily so), appear to be perpetually

juggling approach-approach alternatives. The clinical art of utilizing these models of conflict is to recognize which tendency is dominant within a particular patient and then structure binds that offer only therapeutic alternatives of response. When we do not know which tendency is more predominant, we can offer general binds that are applicable to anyone, such as the following.

Would you like to enter trance now or later? Would you like to enter trance sitting or lying down? Would you like to go into a light, medium, or deep trance?

The patient has free, conscious choice in responding to any of the alternatives offered above. As soon as a choice is made, however, the patient is bound to enter trance. As can be seen from these examples, the question format is particularly well suited for offering binds. When using it with ideomotor signaling, we can frequently formulate an associational network of structured inquiry that can rapidly unravel the dynamics of a problem and resolve it. Cheek and LeCron (1968) have pioneered such lines of structured inquiry for many psychological and psychosomatic conditions.

An example of the therapeutic use of an avoidance-avoidance bind to resolve a symptom of insomnia was the case of a meticulous elderly gentleman who took pride in doing all his own housework - except that he hated to wax floors. After an appraisal of his personality, the senior author told the gentleman that there was an obvious solution to the insomnia problem, but he might not like it. The gentleman politely insisted that he would do whatever was necessary to be able to sleep. The senior author continued to demur, while permitting the gentleman to commit himself further by giving a number of examples of how persistent he was in dealing with difficult problems once he determined he would. He insisted that his word was his bond, and he was used to dealing with unpleasant matters. This clearly confirmed that this man of admirable character was, indeed, well practiced in working through avoidance-avoidance conflicts. His determination in the face of such conflicts was utilized in structuring a therapeutic avoidance-avoidance bind. He was told that if he was not asleep within fifteen minutes of going to bed, he had to get up and wax floors until he felt he could sleep. If he was still not asleep within fifteen minutes, he had to get up again and so continue this procedure until he was asleep. The gentleman later reported that he had well-waxed floors and slept remarkably well.

We may call this situation a therapeutic avoidance-avoidance *bind* because the gentleman was presented with negative alternatives over which he had conscious, voluntary choice. He could choose between the negative alternatives of insomnia or waxing floors. As we study this example a bit further, however, it begins to reveal aspects of a *double bind.* We could conceptualize the gentleman's characterological structure, which enabled him *to persist in the face of difficulties,* as well as his *word was his bond"* as metalevels that bound him automatically to his therapeutic task. These metalevels of his character were utilized in a manner that was outside his normal range of conscious choice and control.

This example illustrates the difficulties in any exact formulation or understanding of the operation of the bind and double bind in actual clinical practice. In general, however, we can say that the more we involve the patients' own associations and learned patterns of response, the more they are likely to experience a bind, double bind, or triple bind as an effective agent in behavior change that is experienced as taking place on an autonomous (unconscious, hypnotic) level.

11b. The Conscious-Unconscious Double Bind

Some of the most fascinating and useful double binds are those that deal with the interface between conscious and unconscious processes (Erickson, 1964; Erickson and Rossi, 1975). These double binds all rest upon the fact that while we cannot control our unconscious, we can receive a message consciously that can initiate unconscious processes. The conscious-unconscious double bind is designed to bypass the limitations of our conscious understanding and abilities so that behavior can be mediated by the hidden potentials that exist on a more autonomous or unconscious level. Any response to the following, for example, requires that the patient experience an inner focus and search that initiates unconscious processes in ways that are usually beyond conscious control.

If your unconscious wants you to enter trance, your right hand will lift all by itself. Otherwise your left hand will lift.

Whether one gets a yes (right hand) or no (left hand) response to this suggestion, one has begun to induce trance, since any truly autonomous response (lifting either hand) implies that a trance exists. If the patient simply sits quietly, and no hand response is evident after a few minutes, the therapist can introduce a further double bind with the following addition.

Since you've been sitting quietly and there is yet no hand response, you can wonder if your unconscious would prefer not to make any effort at all as you go into trance. It may be more comfortable not to have to move or talk or even bother trying to keep your eyes **open.**

At this point the patient's eyes may close and trance become manifest. The eyes may remain open with a passive stare, and there will be continuing body immobility suggestive of the development of trance. If the patient is experiencing difficulty, on the other hand, there will be an uneasy shifting of the body, facial movements, and finally some talk about the problem.

The conscious-unconscious double bind in association with questions, implications, not knowing - not doing, and ideomotor signaling is thus an excellent means of initiating trance and exploring a patient's patterns of response.

In therapy the conscious-unconscious double bind has innumerable uses, all based on its ability to mobilize unconscious processes. The use of the *negative* as described earlier is very useful here.

You*don't* have to listen to me because your unconscious is here and can hear what it needs to, to respond in just the right way.

And it really *doesn't* matter what your conscious mind does because your unconscious can find the right means of coping with that pain [*or whatever*].

You've said you *don't*know how to solve that problem. You are uncertain and confused. Your conscious mind really *doesn't* know what to do. And yet we know that the unconscious does have access to many memories and images and experiences that it can

make available to you in ways that can be most surprising for solving that problem. You *don't* know what all your possibilities are yet. Your unconscious can work on them all by itself. And how will you know when it has been solved? Will the solution come in a dream you will remember, or will you forget the dream but find that the problem is gradually resolving itself in a way that your conscious mind *cannot* understand? Will the resolution come quickly while wide-awake or in a quiet moment of reflection or daydreaming? Will you be at work or at play, shopping or driving your car, when you finally realize it? You really *don't* know, but you certainly can be happy when the solution does come.

In these examples it can be seen how the conscious-unconscious double bind in association with questions and open-ended suggestions can facilitate whatever responses are most suitable for the patient's individuality. All the major cases of this volume illustrate how this form of double bind can be applied to a variety of problems and situations. In all such situations we are depotentiating the patient's conscious, habitual, and presumably more limited patterns in favor of unconscious processes and potentials. If we are willing to identify these unconscious processes with the activity of the nondominant cerebral hemisphere (usually the right - Galin, 1974; Hoppe, 1977) and conscious self-direction and rational processes with the dominant cerebral hemisphere (usually the left), we could say that the conscious-unconscious double bind tends to depotentiate the limitations of the dominant hemisphere and thereby possibly facilitate the potentials of the nondominant. This is particularly the case with the double dissociation double bind, to which we will now turn our attention.

11c. The Double Dissociation Double Bind

Traditionally the concept of dissociation has been used as an explanation of hypnosis. Hypnotic or autonomous behavior takes place outside the patient's immediate range of consciousness and is therefore dissociated from the conscious mind. The senior author has evolved many subtle and indirect means of facilitating dissociations that appear to utilize many entirely normal but alternate pathways of behavior that lead to the same end. All roads lead to Rome is a cliche that expresses the intense obviousness and, therefore, usefulness of this approach. Precisely because alternate pathways to the same response are very obviously true and respectful of the patient's individuality, suggestions that utilize them are very acceptable.

The double dissociation double bind was discovered by the authors (Erickson, Rossi, and Rossi, 1976) when we analyzed the following.

You can as a person awaken, but you do not need to awaken as a body.

[Pause]

You can awaken when your body awakens but without a recognition of your body.

In the first half of this suggestion awakening as a person is dissociated from awakening as a body. In the second half awakening as a person and as a body are dissociated from a recognition of the body. Suggestions that embody such dissociations facilitate hypnotic behavior while also

exploring each individual's unique response abilities. The double dissociation double blind tends to confuse a patient's conscious mind and thus depotentiate his habitual sets, biases, and learned limitations. This sets the stage for unconscious searches and processes that may mediate creative behavior. The following examples suggest the range of its application.

You can dream you're awake even though you're in trance.

[Pause]

Or you can act as if you're in trance even while awake.

You can find your hand lifting without knowing where it is going.

[Pause]

Or you may sense where it is going even though you're not really directing it.

You can make an abstract drawing without knowing what it is.

[Pause]

You can later find some meaning in it even though it does not *seem* related to you personally.

You can speak in trance even though you don't always recognize the meaning of your words.

[Pause]

Or you can remain silent as your head very slowly nods yes or shakes no all by itself in response to my questions.

As can be seen from these examples, the double dissociation double bind is often a potpourri of all sorts of indirect forms of suggestion: implications, contingencies, negatives, open-ended suggestions, apparently covering all possibilities of a class of responses, not knowing, not doing, and so on. Their common denominator is the facilitation of dissociations that tend to depotentiate a patient's habitual conscious sets so that more involuntary levels of response can be expressed. The authors (Erickson, Rossi, and Rossi, 1976) have discussed how this form of the double bind may be related to the neuropsychological concepts formulated by Luria (1973).

A detailed study and assessment of the patient's response to carefully formulated double dissociation double binds can be of great use in planning further hypnotic work. Consider the following, which can provide either an initiation into somnambulistic training or at least a validation of trance.

Now, in a moment your eyes will open but you don't need to awaken. [Pause]

Or you can awaken when your eyes open, but without remembering what happened when they were closed.

This double dissociation double bind has a definite marker indicating that the suggestion has been received and is being acted upon: the eyes opening. When the eyes open, the therapist notes whether (1) there is a simultaneous movement of the body, indicating that the patient is awakening or (2) the patient remains immobile, indicating that trance is continuing. If the patient's body remains immobile when the eyes open, the patient will have a complete memory of all trance events, since that trance continues. The therapist can assess this condition by questioning and then requesting an ideomotor response so the patient's unconscious can firmly validate that a trance is still present (e.g., If you are still in trance your yes finger can lift, your head can slowly nod yes, and so on). An affirmative ideomotor response, indicating that the patient continues to experience trance even with eyes open, is a strong indication that the patient has entered the first stages of somnambulistic training: Patients in this state can in general act as if they are awake, yet they continue to follow suggestions as if they were in a deep trance. The therapist then simply continues this somnambulistic training by proffering further suggestions to deepen their involvement and extend their range of hypnotic responsiveness (automatic talking and writing, visual and auditory hallucinations, and so on).

If, on the other hand, such patients move and speak as if they were perfectly awake when their eyes open, they are apparently acting on the second alternative, and we would assess the validity of the trance by determining the presence of an amnesia for trance events. But what if a patient awakes and there is no amnesia? Does this mean that trance was not experienced? Possibly. More likely, however, such patients will recall only one or two things of such particular significance for them during trance that they attracted conscious attention and so are recalled easily after trance. There will tend to be an amnesia for many other trance events; however, another possibility is that amnesia may be a particularly difficult response for such patients. They may have experienced a genuine trance but for some reason cannot experience the response of amnesia. To assess this possibility the therapist reintroduces trance and then, after another double dissociation double bind, uses another modality as an indication of trance. In the following, for example, body movement (or an inhibiting verbal response) is used as a trance indication instead of amnesia.

Now, in a moment your eyes will open, but you don't need to awaken.

Or you can awaken when your eyes open, but you won't feel like moving your arms for a few minutes [or won't feel like speaking for a few minutes].

Patients who accept the second alternative and awaken can validate the trance by not moving their arms (or speaking) for a few minutes. It is wise to offer trance indicators in this permissive manner. (You *won't feel like* moving your arms) rather than as a challenge (You *won't be able* to move your arms), because the challenge is often taken as an affront by our modern consciousness that takes such hubris in its apparent independence and power.

12. Multiple Levels of Meaning and Communication: The Evolution of Consciousness in Jokes, Puns, Metaphor, and Symbol.

Our five-stage paradigm of the dynamics of trance induction and utilization (Figure 1) illustrates some of the essential processes in what we may call multiple levels of meaning and communication (Erickson and Rossi, 1976). Most literary devices are actually means of initiating unconscious searches and processes to evoke multiple levels of meaning. This is a most interesting and significant aspect of the economy of mental dynamics and the evolution of consciousness. Freud has discussed the antithetical meaning of primal words (Freud, 1910) and the relation of jokes and puns to the unconscious (Freud, 1905). Jokes are of particular value in our approach because they help patients break through their too-limited mental sets and thus initiate unconscious searches for other and perhaps new levels of meaning. Jung has discussed the concept of the *symbol* not as a simple sign of one thing for another, but rather as the best representation of something that is still in the process of becoming conscious (Jung, 1956). The significant factor in all these conceptions is the idea of the *evolution of consciousness.* If patients have problems because of learned limitations, then it is clear that therapeutic processes can be initiated by helping them develop behavioral potentials and new patterns of consciousness that bypass those limitations.

From this point of view we can understand how metaphor and analogy can be something more than artistic devices: They can evoke new patterns and dimensions of consciousness. The very derivation of the word *metaphor (meta,* beyond, over ; *pherin,* to bring, bear) suggests how new meaning developed within the unconscious is brought over to consciousness by means of metaphor. The traditional definition of metaphor is that it is a word or phrase that literally denotes one thing but by analogy suggests another (e.g., a *ship plows* the sea; a *volley* of oaths). In our psychological usage, however, such traditionally literary devices as metaphor, analogy, and simile are understood as means of facilitating the development of insight or new consciousness in the therapeutic transaction. They are essentially stimuli that initiate unconscious searches and processes leading to the creation of new meaning and dimensions of consciousness. Recently Jaynes (1976) has integrated a broad range of data from the fields of psychology, linguistics, neuropsychology, and anthropology which affirmed the hypothesis that metaphor and analogy generate new levels of consciousness.

The senior author has pioneered the use of such approaches to facilitate therapeutic processes in hypnotherapy. His gradual development of the interspersal approach has been the most significant factor in his learning to cultivate multiple levels of meaning and communication as well as enhance the evolution of consciousness. Deterministic as well as nondeterministic processes are both in evidence here. In many of the cases in this book the senior author uses these approaches to facilitate the awareness of certain dynamics that he feels to be at the core of the patient's problems. He uses multiple levels of communication in a highly deterministic way to help the patient recognize certain definite dynamics. In most of these cases, however, the patients also learn entirely new things that neither they nor the senior author could have predicted. It is the

nondeterministic aspect of these approaches that is most exciting in facilitating the evolution of consciousness. Jung has formulated these dynamics in what he calls the *transcendent function:* the integration of conscious and unconscious contents in a manner that facilitates the evolution of new patterns of awareness (Jung, 1960). We presume that many of the practical approaches illustrated by the cases in this volume are actually means of facilitating the evolution of such new patterns of awareness.

Exercises

1. We have previously presented a number of exercises to facilitate the acquisition of skill with most of the indirect forms of suggestion discussed in this chapter (Erickson, Rossi, and Rossi, 1976). So multifaceted are the possibilities of the indirect approaches, however, that one can feel overwhelmed to the point where one does not attempt a systematic beginning in practicing their use. Because of this we strongly suggest that the reader learn to use only a few at a time. The *interspersal approach,* together with all forms *of questions* and *truisms,* for example, can be utilized in any therapeutic interview even without the formal induction of trance. It is highly instructive simply to observe the development of *ayes set* when these approaches are used with the patient's own vocabulary and *frames of reference.* At this level our approach might appear similar to the nondirective, client-centered approach of Rogers (1951).

2. Even without the formal induction of trance one can explore the effectiveness *of ideodynamic process*in *an open-ended* manner with the patient simply by maintaining an attitude of *expectancy* about what can be experienced. It is instructive to note how after a period of five to twenty minutes of such exercises with the eyes closed most subjects will stretch, yawn, and reorient to their bodies when they open their eyes to end the inner work - as if they had been asleep or in trance. Perhaps they have been (Erickson, 1964). We really have no independent criterion for assessing whether they were or not.

3. The next stage of competence probably involves the planned use of the varieties *of compound suggestions.* The therapist needs time and patience to carefully write out ahead of time patterns of *contingency suggestions* and *associational networks.* The use of *shock, surprise,* and *creative moments* can involve a careful study and retrospective analysis of how these phenomena operate spontaneously in everyday life.

4. The use of implications can be facilitated by a careful study of tape recordings of one's therapy sessions. What are the conscious and unconscious implications of both the therapist's and the patient's remarks? After a period of such study one gradually develops more of a consciousness of the implications of words just as one is uttering them. One is then in a position to begin the planned use of implications as a therapeutic approach. The *multiple levels of meaning via jokes, puns,* and *metaphor* now became more easily available.

5. The therapeutic binds and double binds discussed in this chapter are fairly simple to learn, and they provide an almost infinite range of possibilities for exploring psychodynamics and facilitation of hypnotic responsiveness. The therapist newly interested in this area can spend many enjoyable

hours formulating plausible *conscious-unconscious*and *double dissociation double binds* that apparently *cover all possibilities of response*, just as others might spend their time on crossword puzzles. To test one out in clinical practice is a fail-safe procedure, since at worst the patient will probably ignore it and nothing will happen at all. Other forms of the double bind discussed by Watzlawick et al. (1967), Haley (1963, 1973), and the authors (Erickson and Rossi, 1975) still only come to the junior author by happy accident. We are here in the vanguard of our understanding of understanding. Controlled experimental studies as well as interesting clinical examples very much need to be published.

6. The indirect forms of suggestion may make a contribution to the current intriguing debate about writing a computer program to do psychotherapy (Weizenbaum, 1976; Nichols, 1978). Readers with the appropriate experience might explore the possibility that a computer programmed with these hypnotic forms could generate new combinations of suggestions uniquely suitable for specific symptom complexes, personality problems, and altered states of consciousness.

CHAPTER 3

The Utilization Approach: Trance Induction and Suggestion

The senior author (Erickson, 1958, 1959) has distinguished between the formalized ritualistic procedures of trance induction, where the same method is applied mechanically to everyone, and the naturalistic approach, wherein the patient's unique personality and behavior are *utilized* to facilitate trance. In this utilization approach the patient's *attention is fixed* on some important aspect of his own personality and behavior in a manner that leads to the inner focus that we define as therapeutic trance. The patient's habitual conscious sets are more or less depotentiated, and unconscious searches and processes are initiated to facilitate a therapeutic response. In this chapter we will illustrate this utilization approach to trance induction and suggestion with a variety of examples from clinical practice. We will analyze some of the typical approaches to preparing patients for trance experience along with the actual induction and ratification of the trance. In these examples we will focus on how an interaction of *the utilization approach* and the *indirect forms of suggestion* can facilitate a therapeutic outcome in virtually any situation in which the therapist and patient find themselves.

1. Accepting and Utilizing the Patients' Manifest Behavior

The initial step in the utilization approach, as in most other forms of psychotherapy, is to accept the patients' manifest behavior and to acknowledge their personal frames of reference. This openness and acceptance of the patients' worlds facilitate a corresponding openness and acceptance of the therapist by the patients. The following examples taken from the senior author's unpublished and published records (Erickson 1958, 1959) illustrate how the rapport can develop and rapidly lead to an experience of therapeutic trance.

The development of a trance state is an intrapsychic phenomenon, dependent upon internal processes, and the activity of the hypnotist serves only to create a favorable situation. As an analogy, an incubator supplies a favorable environment for the hatching of eggs, but the actual hatching derives from the development of life processes within the egg.

In trance induction, the inexperienced hypnotist often tries to direct or bend the subject's behavior to fit his conception of how the subject should behave. There ought to be a constant minimization of the role of the hypnotist and a constant amplification of the subject's role. An example may be cited of a volunteer subject, used later to teach hypnosis to medical students. After a general discussion of hypnosis, she expressed a willingness to go into a trance immediately. The suggestion was offered that she select the chair and position she felt would be most comfortable. When she had settled herself to her satisfaction, she remarked that she would like to smoke a cigarette. She was immediately given one, and she proceeded to smoke lazily, meditatively watching the smoke drifting upward. Casual conversational remarks were offered about the

pleasure of smoking, of watching the curling smoke, the feeling of ease in lifting the cigarette to her mouth, the inner sense of satisfaction of becoming entirely absorbed just in smoking comfortably and without need to attend to any external things. Shortly, casual remarks were made about inhaling and exhaling, these words timed to fit in with her actual breathing. Others were made about the ease with which she could almost automatically lift her cigarette to her mouth and then lower her hand to the arm of the chair. These remarks were also timed to coincide with her actual behavior. Soon, the words inhale, exhale, lift, and lower acquired a conditioning value of which she was unaware because of the seemingly conversational nature of the suggestions. Similarly, casual suggestions were offered in which the words sleep, sleepy, and sleeping were timed to her eyelid behavior.

Before she had finished the cigarette, she had developed a light trance. Then the suggestion was made that she might continue to enjoy smoking as she slept more and more soundly; that the cigarette would be looked after by the hypnotist while she absorbed herself more and more completely in deep sleep; that, as she slept, she would continue to experience the satisfying feelings and sensations of smoking. A satisfactory profound trance resulted and she was given extensive training to teach her to respond in accord with her own unconscious pattern of behavior.

In this example the initial preparation and facilitation of an optimal frame of reference occurred as the subject listened to a general discussion of hypnosis. The senior author, as a teacher, could not help but use indirect associative focusing and ideodynamic focusing in his general talk about hypnosis. As we saw in the previous chapter, all such general discussions automatically initiate ideodynamic processes that can then serve as the foundation for trance experience.

The fact that this subject volunteered is an indication that this initial preparation was particularly effective for her. One of the joys of working with volunteers from such groups is precisely this form of self-recognition of one's readiness for trance.

Her surprising desire to smoke, once she was settled for trance work, might have been experienced as a disconcerting sign of resistance by a less experienced therapist. Indeed, when this same subject was later used by students, who did not accept her wish to smoke, they were not able to induce trance. The senior author immediately accepted her behavior, however, and even gave her a cigarette. This enhanced their rapport as they were now cooperatively engaged together in her smoking. As she proceeded to smoke lazily, meditatively, we can begin to appreciate how her apparently disruptive behavior of smoking may have been an unconsciously determined means of cooperating with the hypnotic process. For this subject smoking led to an inner meditative mood entirely in keeping with trance induction. The senior author recognized and utilized this meditative mood to facilitate trance *by fixing her attention* even more on her smoking with casual conversational remarks. This casual conversation, of course, provides the senior author with a general context into which he can *intersperse*suggestions about pleasure, ease, inner sense of satisfaction, and *becoming entirely absorbed* in smoking ' *'comfortably without need to attend to any external things.* These interspersed suggestions tended to *depotentiate her habitual waking orientation* even further. The process of *not knowing and not doing* that takes place when we do not have to attend to external things led her to an unconscious search for some new form

of direction and orientation.

This new direction was provided by the senior author with his obvious interest in her smoking behavior. He then utilized her smoking behavior for a process of unconscious conditioning; her inhaling, exhaling, lifting and lowering of her hand became conditioned to following his voice and suggestions. This unconscious conditioning was a way of assessing and reinforcing her response attentiveness. Finally the ideodynamic associative value of words like sleep were then associated with her actual eyelid behavior suggestive of sleep (eyelids closing, fluttering, etc.). Even though both therapist and patient fully recognize that therapeutic trance is not sleep, words evoking the idea of sleep tend to evoke associated behaviors (like comfort and not doing) that tend to facilitate trance.

The process of rapport was further enhanced as he took her cigarette and suggested she might continue to enjoy smoking as she slept more and more soundly. A hallucinatory wish fulfillment of something she obviously enjoyed, such as smoking, was made contingent on sleeping more and more soundly. She was given an expectancy of continued satisfying feelings as she went deeper into trance. This sound utilization of her smoking behavior, together with many indirect forms of suggestion that evoked her own associative processes, then led to more extensive trance training.

Our next example is a particularly vivid illustration of how a highly intellectualized frame of reference attending primarily to external things can be gradually shifted to an internal focus that is more suitable for therapeutic trance.

This patient entered the office in a most energetic fashion and declared at once that he did not know if he was hypnotizable. He was willing to go into a trance if it were at all possible, provided the writer would approach the entire matter in an intellectual fashion rather than in a mystical, ritualistic manner. He declared that he needed psychotherapy for a variety of reasons and that he had tried various schools of psychotherapy extensively without benefit. Hypnosis had been attempted on various occasions and had failed miserably because of mysticism and a lack of appreciation for the intellectual approach.

Inquiry revealed that he felt an intelligent approach signified, not a suggestion of ideas, but questioning him concerning his own thinking and feeling in relation to reality. The writer, he declared, should recognize that he was sitting in a chair, that the chair was in front of a desk, and that these constituted absolute facts of reality. As such, they could not be overlooked, forgotten, denied or ignored. In further illustration, he pointed out that he was obviously tense, anxious, and concerned about the tension tremors of his hands, which were resting on the arms of the chair, and that he was also highly distractable, noticing everything about him.

The writer immediately seized upon this last comment as the basis for the initial cooperation with him. He was told, Please proceed with an account of your ideas and understanding, permitting me only enough interruptions *to insure that I understand fully and that I follow along with you.* For example, you mentioned the chair but obviously you have seen my desk and have been distracted by the objects on it. Please explain fully.

He responded verbosely with a wealth of more or less connected comments about everything in sight. At every slight pause, the writer interjected a word or phrase to direct his attention anew. These interruptions, made with increasing frequency, were as follows: And that paperweight; the filing cabinet; your foot on the rug; the ceiling light; the draperies; your right hand on the arm of the chair; the pictures on the wall; the changing focus of your eyes as you glance about; the interest of the book titles; the tension in your shoulders; the feeling of the chair; the disturbing noises and thoughts; weight of hands and feet; weight of problems, weight of desk; the stationery stand; the records of many patients; the phenomena of life, of illness, of emotion, of physical and mental behavior; the restfulness of relaxation; the need to attend to one's needs; the need to attend to one's tension while looking at the desk or the paperweight or the filing cabinet; the comfort of withdrawal from the environment; fatigue and its development; the unchanging character of the desk; the monotony of the filing cabinet; the need to take a rest; the comfort of closing one's eyes; the relaxing sensation of a deep breath; the delight of learning passively; the capacity for intellectual learning by the unconscious. Various other similar brief interjections were offered, slowly at first and then with increasing frequency.

Initially, these interjections were merely supplementary to the patient's own train of thought and utterances. At first, the effect was simply to stimulate him to further effort. As this response was made, it became possible to utilize his acceptance of stimulation of his behavior by a procedure of pausing and hesitating in the completion of an interjection. This served to effect in him an expectant dependency upon the writer for further and more complete stimulation.

As this procedure was continued, gradually and unnoticeably to the patient his attention was progressively directed to inner subjective experiential matters. It then became possible to use almost directly a simple, progressive relaxation technique of trance induction and to secure a light medium trance.

Throughout therapy, further trance inductions were basically comparable, although the procedure became progressively abbreviated.

The patient's initial statement that he did not know if he was hypnotizable is an important admission of his availability for trance. As we saw in the previous chapter, not knowing and not doing are actually an important condition for trance experience. This highly intellectualized individual is admitting there is a place where he does not know, a place where his habitual sets and frames of reference are not stable - hypnosis is a place where these habitual, and obviously in some way inadequate mental frameworks can be bypassed so that the needed psychotherapy can take place.

The patient then states his conditions for trance experience. The writer (the senior author) must eschew all mystical and ritualistic means and use an intellectual approach. The patient's intellectual orientation is obviously the ability that any sensible therapist would assess as most suitable for utilization.

The patient then describes his distractable state, and the senior author immediately utilizes it as a basis for the initial cooperation with him. He encourages the patient to continue with an account

of his ideas to ensure that I understand fully and that I follow along with you. This is an unrecognized interspersed suggestion that means *understanding and following* are important in therapy. Just as the therapist initially understands and follows the patient, so will the patient soon come to understand and follow the therapist. Rapport, response attentiveness, and an optimal attitude for creating a therapeutic frame of reference are all implied and thereby facilitated by this initial suggestion and acceptance of the patient's behavior.

The senior author's request that the patient explain fully is actually an unrecognized means of focusing and fixing the patient's attention onto a prominent aspect of his own behavior (distracted by objects) that he himself pointed out. Since the patient pointed out this aspect of his own behavior, it must hold some special interest for him and thus can serve as an ideal means of holding his attention. This is a curious situation that may involve a double bind for this particular patient: His distractibility is used to undistract, to focus his attention.

The senior author now gingerly interacts with the patient by redirecting his attention anew at every pause as a means of cooperating with him, and at the same time, enhancing his response attentiveness. By very gradual steps the senior author builds an associative network that leads the patient from the paperweight and filing cabinet to the delight of learning passively and the capacity for intellectual learning by the unconscious. The shift in focus is from the outer to the inner, which is in keeping with trance work. The shift is facilitated by a continuing utilization of the patient's intellectual approach, with the emphasis on learning passively and the unconscious learning. The passivity and unconscious aspects of trance experience are thus associated with the learning that the patient already accepts and knows how to do; it is thus much easier for the patient to accept passivity and the unconscious when it is associated with learning. In this shift from an outer to an inner focus the senior author has a great opportunity to intersperse many forms of indirect associative focusing (e.g., the phenomena of life, of illness, of emotion, of physical and mental behavior) and indirect ideodynamic focusing (e.g., the restfulness of relaxation . . . the comfort of withdrawal from the environment, fatigue and its development). This can facilitate trance induction by initiating unconscious searches and processes that could evoke partial aspects of trance experience as well as a review of the patient's problems.

As the therapist continued to utilize the patient's own train of thought and utterances, his response attentiveness was further enhanced and a greater degree of expectant dependency was experienced by the patient as he now began to look to the therapist for further direction into inner subjective experiential matters, where his psychological problems were.

A similar approach was used in the following case, which the reader should now find easy to analyze in terms of the dynamics we have presented.

Essentially the same procedure was employed with a male patient in his early 30' s who entered the office and began pacing the floor. He explained repetitiously that he could not endure relating his problems sitting quietly or lying on a couch. He had repeatedly been discharged by various psychiatrists because they accused him of lack of cooperation. He asked that hypnotherapy be employed, if possible, since his anxieties were almost unendurable and always increased in intensity in a psychiatrist's office making it necessary for him to pace the floor constantly.

Further repetitious explanation of his need to pace the floor was finally successfully interrupted by the question, Are you willing to cooperate with me *by continuing to pace the floor, even as you are doing now?* His reply was a startled, Willing? Good God, man! I've got to do it if I stay in the office.

Thereupon, he was asked to permit the writer to participate in his pacing by the measure of directing it in part. To this he agreed rather bewilderedly. He was asked to pace back and forth, to turn to the right, to the left, to walk away from the chair, and to walk toward it. At first these instructions were given in a tempo matching his step. Gradually, the tempo of the instructions was slowed and the wording changed to Now turn to the right away from the chair in which you can sit; turn left toward the chair in which you can sit; walk away from the chair in which you can sit; walk toward the chair in which you can sit. etc. With this wording, a foundation was laid for more cooperative behavior.

The tempo was slowed still more and the instructions again varied to include the phrase, the chair which you will soon approach as if to seat yourself comfortably. This in turn was altered to the chair in which you will shortly find yourself sitting comfortably.

His pacing became progressively slower and more and more dependent upon the writer's verbal instructions until direct suggestions could be given that he seat himself in the chair and go deeper and deeper into a profound trance as he related his history.

Approximately 45 minutes were spent in this manner inducing a medium trance that so lessened the patient's tension and anxiety that he could cooperate readily with therapy thereafter.

The value of this type of Utilization Technique lies in its effective demonstration to the patient that he is completely acceptable and that the therapist can deal effectively with him regardless of his behavior. It *meets both the patient's presenting needs and it employs as the significant part of the induction procedure the very behavior that dominates the patient.*

The senior author's question, Are you willing to cooperate with me *by continuing to pace the floor, even as you are doing* now? is an unusually fecund example of the use of a number of indirect hypnotic forms in a single sentence. Being a*question,* it immediately *fixes the patient's attention* and sends him on an *inner search* for an appropriate response. It is an excellent *compound suggestion* that associates an important suggestion about cooperation with his ongoing behavior of pacing the floor. Pacing the floor constantly was the patient's own *ability that was rapidly assessed, accepted, and utilized* to facilitate *ayes set.* The question came as a bit of *a shock and surprise that depotentiated his dominant mental set* about his own resistance and startled him into a strong exclamation of his need to cooperate.*Rapport* was thus strongly established, and therapy structured as a joint endeavor. With such a strong immediate rapport, a high *expectation* was set in motion, heightening the patient's *response attentiveness* to his own internal states as well as to the therapist's further suggestions. By a gradual process of association and unconscious conditioning this response attentiveness was heightened even further, so the patient was finally able to accept suggestions to sit down and go even deeper into himself so that he could relate his history in a state of deep absorption that is described as profound trance.

The beginning therapist who is just learning to integrate the utilization approach with the indirect forms of suggestion may initially feel a bit overwhelmed by these examples, which seem to require such quick wits and a complete command of the material. In practice, however, most patients are desperately searching for help and are very willing to cooperate if they are given an opportunity, as indicated by the following example.

Another subject, a graduate in psychology, experienced great difficulty in going into a deep trance. After several hours of intensive effort, she timidly inquired if she could advise on technique, even though she had no other experience with hypnosis. Her offer was gladly accepted, whereupon she gave counsel: You're talking too fast on that point; you should say that very slowly and emphatically and keep repeating it. Say that very rapidly and wait awhile and then repeat it slowly; and please, pause now and then to let me rest, and please don't split your infinitives. with her aid, a profound, almost stuporous trance was secured in less than thirty minutes. Thereafter, she was employed extensively in a great variety of experimental work and was used to teach others how to induce deep trances.

Acceptance of such help is neither an expression of ignorance nor of incompetence; rather, it is an honest recognition that deep hypnosis is a joint endeavor in which the subject does the work and the hypnotist tries to stimulate the subject to make the necessary effort. It is an acknowledgment that no person can really understand the individual patterns of learning and response of another. While this measure works best with highly intelligent, seriously interested subjects, it is also effective with others. It establishes a feeling of trust, confidence, and active participation in a joint task. Moreover, it serves to dispel misconceptions of the mystical powers of the hypnotist and to indirectly define the respective roles of the subject and the hypnotist.

This acceptance and utilization of the patient's help is the cardinal feature of our approach, which contrasts sharply with the older, authoritarian methods that are still ingrained in the imagination of the laity and the popular press. The earlier, misguided approach that makes trance experience synonymous with passive obedience is, unfortunately, still being promulgated by stage hypnotists. More than a generation ago, however, the senior author illustrated how the patient's cooperation and self-control are of essence in good hypnotic work, as can be seen in the utilization of emergency situations described in the following section.

2. Utilizing Emergency Situations

Emergency situations are invariably trance-inducing. Cheek (Cheek and LeCron, 1968; Cheek, 1959, 1966, 1969, 1974) has illustrated how many iatrogenic problems and neurotic symptoms can be learned by overhearing unfortunate remarks during emergency and stress situations when the patient had lapsed into a spontaneous trance (as a primitive protective response to danger) and was consequently in an unusually heightened state of suggestibility.

The senior author has illustrated how such emergency situations can be utilized to gradually introduce therapeutic suggestions. Two examples with his own children are as follows.

Seven-year-old Allan fell on a broken bottle and severely lacerated his leg. He came rushing into the kitchen crying loudly from pain and fright, shouting, It's bleeding, it's bleeding!

As he entered the kitchen, he seized a towel and began swabbing wildly to wipe up the blood. When he paused in his shouting to catch his breath, he was urgently told, Wipe up that blood; wipe up that blood; use a bath towel; use a bath towel; use a bath towel; a bath towel, not a hand towel, a bath towel. and one was handed to him. He dropped the towel he had already used. He was immediately told urgently and repetitiously, Now wrap it around your leg, wrap it tightly, wrap it tightly.

This he did awkwardly but sufficiently effectively. Thereupon, with continued urgency, he was told, Now hold it tightly, hold it tightly, let's get in the car and go to the doctor's office; hold it tightly.

All the way to the surgeon's office, careful explanation was given him that his injury was really not large enough to warrant as many stitches as his sister had had at the time of her hand injury. However, he was urgently counselled and exhorted that it would be entirely his responsibility to see to it that the surgeon put in as many stitches as possible. All the way there, he was thoroughly coached on how to emphatically demand his full rights.

Without awaiting any inquiry, Allan emphatically told the nurse at the surgeon's office that he wanted 100 stitches. She merely said, This way, sir, right to the surgery. Allan was told, as she was followed, That's just the nurse. The doctor is in the next room. Now don't forget to tell him everything just the way you want it.

As Allan entered the room, he announced to the surgeon. I want 100 stitches. See! Whipping off the towel, he pointed at his leg and declared, Right there, 100 stitches. That's a lot more than Betty Alice had. And don't put them too far apart. And don't get in my way. I want to see. I've got to count them. And I want black thread, so you can see it. Hey, I don't want a bandage. I want stiches!

It was explained to the surgeon that Allan understood well his situation and needed no anesthesia. To Allan, the writer explained that his leg would first have to be washed. Then he was to watch the placing of the sutures carefully to make sure they were not too far apart; he was to count each one carefully and not to make any mistakes in his counting.

Allan counted the sutures and rechecked his counting while the surgeon performed his task in puzzled silence. He demanded that the sutures be placed closer together and complainingly lamented the fact that he would not have as many as his sister. His parting statement was to the effect that, with a little more effort, the surgeon could have given him more sutures.

On the way home, Allan was comforted regarding the paucity of the sutures and adequately complimented on his competence in overseeing the entire procedure so well. It was also suggested that he eat a big dinner and go to sleep right afterwards. Thus his leg could heal faster and he would not have to go to the hospital the way his sister did. Full of zeal, Allan did as

suggested.

No mention of pain or anesthesia was made at any time nor were any comforting reassurances offered. Neither was there any formal effort to induce a trance. Instead, various aspects of the total situation were utilized to distract Allan's attention completely away from the painful considerations and to focus it upon values of importance to a seven-year-old boy in order to secure his full, active cooperation and intense participation in dealing with the entire problem adequately.

In situations such as this, the patient experiences a tremendously urgent need to have something done. Recognition of this need, and a readiness to utilize it by doing something in direct relationship to the origin of the need, constitutes a most effective type of suggestion in securing the patient's full cooperation for adequate measures.

Little Roxanna came into the house sobbing, distressed by an inconsequential (but not to her) scratch upon her knee. Adequate therapy was not assurance that the injury was too minor to warrant treatment, nor even the statement that she was mother's brave little girl and that mother would kiss her and the pain would cease and the scratch would heal. Instead, effective therapy was based upon the utilization of the personality need for something to be done in direct relationship to the injury. Hence, a kiss *to the right*, a kiss *to the left* and a kiss *right on top* of the scratch effected for Roxie an instantaneous healing of the wound and the whole incident became a part of her thrilling historical past.

This type of technique based upon the utilization of strong personality needs is effective with children and adults. It can readily be adapted to situations requiring in some way strong, active, intense responses and participation by the patient.

As can be seen from these examples, the hypnotherapist is continually utilizing the patient's own internal frames of reference even in such outer emergency situations. Further illustrations of this all-important use of the patient's inner realities are presented in the next section.

3. Utilizing the Patient's Inner Realities

The utilization of patients' outer manifest behaviors can be generalized to an acceptance and utilization of their inner realities - their thoughts, feelings, and life experiences. The senior author illustrates this in the following.

Another type of utilization technique is the employment of the patient's inner, as opposed to outer, behavior; that is, using his thoughts and understandings as the basis for the induction procedure. This technique has been employed experimentally and also in therapeutic situations where the patient's type of resistances made it advisable. It has also been effectively used on naive subjects. Ordinarily, good intelligence and some degree of sophistication as well as earnestness of purpose are required.

The procedure is relatively simple. The experimental or therapeutic subject is either asked or allowed to express freely his thoughts, understandings, and opinions. He is then encouraged to speculate aloud more and more extensively upon what could be the possible course of his thinking and feeling if he were to develop a trance state. As the patient does this, or even if he merely protests the impossibility of such speculation, his utterances are repeated after him in their essence as if the operator were either earnestly seeking further understanding or confirming his statements. Thus, further comment by the subject is elicited and repeated in turn by the operator. In the more sophisticated subject, there tends to be greater spontaneity; but occasionally the naive, even uneducated subject may prove to be remarkably responsive.

With this technique, the patient's utterances may vary greatly from one instance to another, but the following example is given in sufficient detail to illustrate the method.

This patient, in seeking psychiatric help, declared, I've made no progress at all in three years of psychoanalysis, and the year I spent in hypnotherapy was also a total loss. I didn't even go into a trance. I tried hard enough. I just got nowhere. I've been referred to you and I don't see much sense in it. Probably another failure. I just can't conceive of myself going into a trance. I don't even know what a trance is. These remarks, together with the information received previously from the referring physician, suggested the possibility of employing the woman's own verbalization as the induction procedure.

The writer's utterances are in italics:

You really can't conceive of what a trance is - no, I can't, what is it? - *yes, what is it!* - a psychological state, I suppose - *A psychological state you suppose, what else!* - I don't know - *you really don't know* - no, I don't - *you don't, you wonder, you think* - think what - *yes, what do you think, feel, sense?* - (pause) - I don't know - *but you can wonder* - do you go to sleep? - *no, tired, relaxed, sleepy* - really tired - *so very tired and relaxed, what else?* - I'm puzzled - *puzzles you, you wonder, you think, you feel, what do you feel?* - my eyes - *yes, your eyes, how?* - they seem blurred - *blurred, closing* - (pause) - they are closing-*closing, breathing deeper* - (pause) - *tired and relaxed, what else?* - (pause) - *sleep, tired, relaxed, sleep, breathing deeper* - (pause) - *what else* - I feel funny - *funny, so comfortable, really learning* - (pause) - *learning, yes, learning more and more* - (pause) - *eyes closed, breathing deeply, relaxed, comfortable, so very comfortable, what else?* - (pause) - I don't know - *you really don't know, but really learning to go deeper and deeper* - (pause) - too tired to talk, just sleep - *maybe a word or two* - I don't know (spoken laboriously) - *breathing deeper and you really don't know, just going deeper, sleeping soundly, more and more soundly, not caring, just learning, continuing ever deeper and deeper and learning more and more with your unconscious mind.*

From this point on it was possible to deal with her simply and directly without any special elaborations of suggestions. Subsequent trances were secured through the use of posthypnotic suggestions.

The above is simply a condensation of the type of utterances utilized to induce trance. In general, there is much more repetition, usually only of certain ideas, and these vary from patient to patient.

Sometimes this technique proves to be decidedly rapid. Frequently with anxious, fearful patients, it serves to comfort them with a conviction that they are secure, that nothing is being done to them or being imposed upon them, and they feel that they can comfortably be aware of every step of the procedure. Consequently, they are able to give full cooperation which would be difficult to secure if they were to feel that a pattern of behavior was being forcibly imposed upon them.

As can be seen from the above, the patient's experience of *not knowing,* I don't know what trance is, can be an ideal starting point for initiating trance and the exploration of inner realities. The following is a further illustration of how a patient's life experiences can be used to facilitate trance induction.

A volunteer subject at a lecture before a university group declared, I was hypnotized once several years ago. It was a light trance, not very satisfactory, and while I would like to cooperate with you, I'm quite certain that I can't be hypnotized. Do you recall the physical setting of that trance? Oh yes, it was in the psychology laboratory of the university I was then attending. Could you, as you sit here, recall and describe to me the physical setting of that trance situation?

He agreeably proceeded to describe in detail the laboratory room in which he had been lightly hypnotized, including a description of the chair in which he had sat, and a description of the professor who had induced the trance. This was followed by a comparable response to the writer's request that he describe in as orderly and as comprehensive a fashion as possible his recollection of the actual suggestions given him at that time and the responses he made to them.

Slowly, thoughtfully, the subject described an eye closure technique with suggestions of relaxation, fatigue, and sleep. As he progressed in verbalizing his recollections, his eyes slowly closed, his body relaxed, his speech became slower and more hesitant; he required increasingly more prompting until it became evident that he was in a trance state. Thereupon, he was asked to state where he was and who was present: He named the previous university and the former professor. Immediately, he was asked to listen carefully to what the writer had to say also, and he was then employed to demonstrate the phenomena of the deep trance.

The junior author has found that questions focusing on memories can be a reliable means of assessing the patient's availability for trance and frequently a fine means of facilitating the actual induction of trance. When one woman was asked about her earliest memory, for example, she first responded with one that was long familiar to her. When she was encouraged to explore further, she paused for a few moments, manifesting that inner focus we call the common everyday trance, and then quietly remarked how she seemed to be looking up at a bright light, with nothing else in focus. A moment later her left leg began levitating, while the rest of her body remained immobile but noticeably relaxed. She then reported that she felt a scream building up in her throat. With that she suddenly shook her head, shuffled her body, and obviously reoriented to the awake state. In her inner search for an earlier memory she had spontaneously fallen into a trance and momentarily experienced a genuine age regression to infancy, when her visual field and her body were apparently not entirely under voluntary control, and she felt herself about to cry as an infant might. That frightened her, so she spontaneously reoriented to the awake state.

Although we do not often get responses as dramatic as this, we frequently find that questions focusing patients on an inner review of their lives and activities facilitate that inner search and the unconscious processes in a manner that leads to a recognizably therapeutic trance.

4. Utilizing the Patient's Resistances

The unfortunate dominance-submission view of hypnosis is probably the basis of much of the so-called resistance to hypnosis. Because of this the senior author developed many utilization approaches and indirect forms of suggestion to cope with this resistance. His approach is essentially the same as that outlined in the earlier section, where he first recognizes and accepts the patient's manifest behavior as a foundation for establishing rapport, and then gradually focuses the patient inward.

Many times, the apparently active resistance encountered in subjects is no more than an unconscious measure of testing the hypnotist's willingness to meet them halfway instead of trying to force them to act entirely in accord with his ideas. Thus, one subject, who had been worked with unsuccessfully by several hypnotists, volunteered to act as a demonstration subject. When her offer was accepted, she seated herself on the chair facing the audience in a stiffly upright, challenging position. This apparently unpropitious behavior was met by a casual, conversational remark to the audience that hypnosis was not necessarily dependent upon complete relaxation or automatism, but that hypnosis could be induced in a willing subject if the hypnotist was willing to fully accept the subject's behavior. The subject responded to this by rising and asking if she could be hypnotized standing up. Her inquiry was countered by the suggestion, Why not demonstrate that it can be? A series of suggestions resulted in the rapid development of a deep trance. Inquiries by the audience revealed that she had read extensively on hypnosis and objected strenuously to the frequently encountered misconception of the hypnotized person as a passively responsive automaton, incapable of self-expression. She explained further that it should be made clear that spontaneous behavior was fully as feasible as responsive activity and that utilization of hypnosis could be effected by recognition of this fact.

It should be noted that the reply, Why not demonstrate that it can be? constituted an absolute acceptance of her behavior, committed her fully to the experience of being hypnotized, and ensured her full cooperation in achieving her own purposes as well as those of the hypnotist.

Throughout the demonstration, she frequently offered suggestions to the author about what he might next ask her to demonstrate, sometimes actually altering the suggested task. At other times, she was completely passive in her responses.

Again we see how an apparently simple question with a negative - Why *not* demonstrate that it can be? - immediately accepts and utilizes the patient's resistance, while initiating her into an inner search that evokes partially conscious and partially unconscious processes leading to hypnotic responses. We can see that her so-called resistance is really not a resistance so much as it is a perfectly reasonable reaction against the erroneous dominance-submission view of hypnosis.

We believe that most so-called resistances have some reasonable basis within the patient's own frame of reference. *Resistance is usually an expression of the patient's individuality*! The therapist's task is to understand, accept, and utilize that individuality to help patients bypass their learned limitations to achieve their own goals. This example is a particularly clear illustration of how a patient is really in control, while the therapist is simply a provider of useful stimuli and frames of reference that help a patient experience and express new potentialities. We see how it can be perfectly appropriate for the patient to reject or modify the therapist's suggestions in order to more adequately meet the patient's needs.

In the following example the senior author makes extensive use of the indirect forms of suggestion to utilize the patient's resistance in order to facilitate trance and hypnotic responsiveness. It is an unusually clear illustration of that curious blend of both leading and following the patient that is so characteristic of the senior author's approach.

One often reads in the literature about subject resistance and the techniques employed to circumvent or overcome it. In the author's experience, the most satisfactory procedure is that of accepting and utilizing the resistance as well as any other type of behavior, since properly used they can all favor the development of hypnosis. This can be done by wording suggestions in such a fashion that a positive or a negative response, or an absence of response, are all defined as responsive behavior. For example, a resistive subject who is not receptive to suggestions for hand levitation can be told, Shortly your right hand, or it may be your left hand, will begin to lift up, or it may press down, or it may not move at all, but we will wait to see just what happens. Maybe the thumb will be first, or you may feel something happening in your little finger, but the really important thing is not whether your hand lifts up or presses down or just remains still; rather, it is your ability to sense fully whatever feelings may develop in your hand.

With such wording absence of motion, lifting up, and pressing down are all covered, and any of the possibilities constitutes responsive behavior. Thus a situation is created in which the subject can express his resistance in a constructive, cooperative fashion; manifestation of resistance by a subject is best utilized by developing a situation in which resistance serves a purpose. Hypnosis cannot be resisted if there is no hypnosis attempted. The hypnotist, recognizing this, should so develop the situation that any opportunity to manifest resistance becomes contingent upon hypnotic responses with a localization of all resistance upon irrelevant possibilities. The subject whose resistance is manifested by failure to levitate his hand can be given suggestions that his right hand will levitate, his left hand will not. To resist successfully, contrary behavior must be manifested. The result is that the subject finds himself responding to suggestion, but to his own satisfaction. In the scores of instances where this measure has been employed, less than a half dozen subjects realized that a situation had been created in which their ambivalence had been resolved. One writer on hypnosis naively employed a similar procedure in which he asked subjects to resist going into a trance in an effort to demonstrate that they could not resist hypnotic suggestion. The subjects cooperatively and willingly proved that they could readily accept suggestions to prove that they could not. The study was published in entire innocence of its actual meaning.

Whatever the behavior offered by the subject, it should be accepted and utilized to develop further

responsive behavior. Any attempt to correct or alter the subject's behavior, or to force him to do things he is not interested in, militates against trance induction and certainly against deep trance experience. The very fact that a subject volunteers to be hypnotized and then offers resistance indicates an ambivalence which, when recognized, can be utilized to serve successfully the purposes of both the subject and the hypnotist. Such recognition of and concession to the needs of the subject and the utilization of his behavior do not constitute, as some authors have declared, an unorthodox technique based upon clinical intuition; instead, such an approach constitutes a simple recognition of existing conditions, based upon full respect for the subject as a uniquely functioning personality.

The reader will recognize the use of many indirect forms of suggestion such as covering all possibilities of a class of responses, contingency suggestions, and double binds in the above. These approaches are integrated by the senior author in the following example of a more comprehensive approach that can be adapted to practically any situation.

Another comparable Utilization Technique has been employed experimentally and clinically on both naive and experienced subjects. It has been used as a means of circumventing resistances, as a method of initial trance induction, and as a trance reinduction procedure. It is a technique based upon an immediate and direct elicitation of meaningful but unconsciously executed behavior which is separate and apart from consciously directed activity except that of interested attention. The procedure is as follows:

Depending upon the subject's educational background, a suitable casual explanation is given relating general concepts of the conscious and of the unconscious or subconscious minds. Similarly, a casual though carefully instructive explanation is given of ideomotor activity with a citing of familiar examples, including hand levitation.

Then, with utter simplicity, the subject is told to sit quietly, to rest his hands palm down on his thighs, and to listen carefully to a question that will be asked. This question, it is explained, can be answered only by his unconscious mind, not by his conscious mind. He can, it is added, offer a conscious reply, but such a reply will be only a conscious statement and not an actual reply to the question. As for the question itself, it can be any of several pertinent questions, and it is of no particular significance to the person. Its only purpose is to give the unconscious mind an opportunity to manifest itself in the answer given. The further explanation is offered that the answer to the question asked the unconscious mind will be an ideomotor response of one or the other hand lifting upward, that of the left signifying no, and that of the right signifying yes.

The question is then presented: Does your unconscious mind think that you can go into a trance? Further collaboration is offered: Consciously you cannot know what your unconscious mind thinks or knows. But your unconscious mind can let your conscious mind discover what it thinks or understands by the simple process of causing a levitation of either the right or the left hand. Thus your unconscious mind can communicate in a visibly recognizable way with your conscious mind. Now just watch your hands and see what the answer is. Neither you nor I know what your unconscious mind thinks, but as you see one or the other of your hands lifting, you will know.

If there is much delay, additional suggestions can be given: One of your hands is lifting. Try to notice the slightest movement, try to feel and to see it, to enjoy the sensation of its lifting and be pleased to learn what your unconscious thinks.

Regardless of which hand levitates, a trance state frequently of the somnambulistic type supervenes simultaneously. Usually, it is advisable to utilize, rather than to test, the trance immediately since the subject tends to arouse promptly. This is often best done by remarking simply and casually. It is very pleasing to discover that your unconscious can communicate with your conscious mind in this way. There are many other things that your unconscious can learn to do. For example, now that it has learned that it can develop a trance state and to do so remarkably well, it can learn various trance phenomena. For instance, you might be interested in - . The needs of the situation can then be met.

This technique centers around the utilization of the subject's interest in his own unconscious activity. A yes or no situation is outlined concerning thinking, with action contingent upon that thinking and constituting an overt unconscious communication, a manifestation basic to, and an integral part of a hypnotic trance. In other words, it is necessary for the subject to go into a trance in order to discover the answer to the question.

Experienced subjects approached with this technique have recognized the situation immediately: How interesting! No matter which answer you give, you have to go into a trance first.

Willing subjects disclose their unaffected interest from the beginning. Resistant subjects manifest their attitudes by difficulty in understanding the preliminary explanations, by asking repeatedly for instructions, and then by an anticipation of hand levitation by lifting the left hand voluntarily. Those subjects who object to trance induction in this manner tend to awaken at the first effort to test or to utilize the trance. Most of them, however, will readily go back into the trance when told, And you can go into a trance just as easily and quickly as your unconscious answered that question just by continuing to watch as your unconscious mind continues to move your hand up toward your face. As your hand moves up, your eyes will close, and you will go into a deep trance. In nearly all instances, the subject then develops a trance state.

An essential component of this technique is an attitude of utter expectancy, casualness, and simplicity on the part of the operator, which places the responsibility for any developments entirely upon the subjects.

The senior author begins by carefully *assessing the patient's background* and then uses concepts that fit the patient's frames of reference. He uses a process of *indirect associative focusing* as he discusses the concepts of the conscious and unconscious to lay a foundation for his later use of the *conscious-unconscious double bind.* Patients' *expectations* are then heightened as they are asked to prepare for a *question* that initiates an *inner search* for*unconscious processes* that will lead to an *ideomotor or ideosensory response.* There is an emphasis on the pleasure of learning and a continual *utilization of each patient's areas of interest.* The conscious-unconscious double bind is structured so that any response made is *contingent* on the development of trance. This first successful experience with ideomotor activity is then generalized into a recognizable trance

induction with an *implied directive* ,As your hand moves up, your eyes will close, and you will go into a deep trance.

An example that dramatically illustrates how trance behavior can be manifest, even when the patient resists the idea of being in a trance, was recorded during a workshop of the American Society of Clinical Hypnosis in 1960. The senior author was giving a talk on the dynamics of hypnosis. During such a talk there is ample opportunity to intersperse many ideodynamic suggestions that cannot help but activate the described ideodynamic process at least partially within most members of the audience. After giving a demonstration of hand levitation, he describes the following occurrence:

One of the subjects felt very, very strongly that she was not a good subject. As I observed that intensely rapt attention *(response attentiveness)* she was giving me, however, I could feel very strongly that she was a good subject. So I asked her to 'Give your unconscious mind the privilege of manifesting in some way that you are a good hypnotic subject but that you will not consciously recognize it. At the same time you can continue to function well at the conscious level. I might add that the manifestation might be obvious to the audience but not to you.' Even as she continued to focus closely on me and not the audience or anything else, she said, Tm not a good subject, and I don't believe you can convince me.

At this point I was utilizing her resistance to let her think she was awake and not in a somnambulistic trance. But the very intensity of her absorption in watching my every move and following everything I said was a clue to her somnambulistic condition.

I asked her again if I could put her into a trance, but she shook her head 'no,' she wouldn't cooperate. At that moment her left hand began levitating, but she did not see it because she was looking over toward me on the right.

She laughed and joked with the doctors in the audience and said she did not like to feel she was being uncooperative, but she did feel she couldn't go into a trance. Remember, I told her to function very well at the conscious level and very well at the unconscious level. And there she was talking to me and talking to the audience in this fashion. I indicated to one of the doctors in the audience that he should come up and pinch her levitated left hand. He found that she had a total anesthesia in that left hand, that she was willing to swear to the group that she was wide awake and that she couldn't possibly be in a trance. The doctor then came around and pinched her right hand, and she said, 'Ouch, that hurts! Naturally I would feel a pinch.' She was pinched again on the left hand but did not feel it.

What I wanted to demonstrate to the doctors there, and what I want to stress to you, is the separation of functioning that goes on all the time in the human body, separation at an intellectual level, separation at an emotional level, separation at a sensory level, just as you have forgotten the shoes on your feet at this moment and the glasses on your face.

This dramatic example illustrates the importance of the hypnotherapist's learning to recognize that state of rapt response attentiveness when the patient is, for all practical purposes, already in a

trance state fixated on the therapist, no matter what may be said to the contrary. When the senior author observes this state of intense absorption on himself, he offers patients one or more forms of indirect suggestion that provides them with an opportunity for a hypnotic response. In this case he used a form of the conscious-unconscious double bind that enabled her unconscious to select a hypnotic manifestation (hand levitating that she had already been primed for by watching others), while allowing her conscious mind to keep its usual patterns of functioning. She was thus able to keep her resistance while manifesting good hypnotic responsiveness.

The following is another illustration wherein trance was induced even under the most resistant conditions, where the subject was a professional actor attempting to simulate hypnosis. Unknown to the senior author, at a lecture demonstration before a medical group, one of the subjects was a trained actor. He watched the other subjects carefully and then, in accord with previous secret arrangements with several people in the audience, he simulated hypnosis and demonstrated anesthesia, negative and positive auditory and visual hallucinations, and developed uncontrollable sneezing upon hallucinating goldenrod in bloom, at the request of one of the conspirators, relayed through the senior author. However, the senior author noted that the actor's manifestation of catalepsy was faulty, and his time relationships were wrong. Minor startle reflexes were noted, too, and the subject was observed to be controlling the involuntary tendency to turn his head toward the author when addressed from the side. Accordingly, he was asked to demonstrate hand levitation in response to carefully given suggestions. The actor did not show the usual time lag in response to suggestions of a sudden little jerk or quiver. This served to convince the senior author that he was being hoaxed.

Accordingly, the subject was furnished with pencil and paper and instructed to do automatic writing and to do this automatic writing in the correct style of true automatic writing. The actor had never witnessed automatic writing; however, as he began writing, suggestions were offered of writing slowly and better and better, writing automatically the sentence, *'This* is a beautiful day in June.' The word this" was repeated four times with strong intonations to fixate consciousness on it, while the rest of the sentence was said more softly and swiftly, so that it would tend to be missed by consciousness and fall into the unconscious. The word this was written in his ordinary script, but the rest of the sentence was written in the characteristic script of automatic writing. The actor subject was now beginning to experience some genuine trance behavior without realizing it. As he finished writing, the paper and pencil were removed from his sight and he was asked to awaken *with an amnesia for trance events.*He roused immediately and was asked to discuss hypnosis for the audience. With great satisfaction he proceeded to expose the hoax perpetrated upon the senior author to the amazement of the audience in general and the glee of the conspirators. The subject talked freely of what he had done and demonstrated his ability to sneeze at will.

After he had recounted everything except the automatic writing, this was shown to him and he was asked what he thought of it. He read the sentence aloud, stated that it was just a simple statement with no particular relevancy. Asked about the script, he observed that it appeared to be somewhat labored and juvenile. It soon became apparent to everyone that he had a total amnesia for the writing, that he was genuinely curious about the writing and why he was being questioned about it. When his amnesia had been adequately demonstrated, he was asked to duplicate that

writing exactly, He agreed readily, but as he took the pencil and set it to the paper, it was at once obvious that he had developed a trance state again (repeating trance behavior tends by association to reinduce trance). After he had written the sentence this second time, he was aroused with instructions for an amnesia for trance events. As he aroused, he resumed his mockery of the author for being so easily deceived. Again he was shown the writing. He recognized that he had seen the one sentence a few moments ago, but there was a second sentence that he had not seen before.

He was allowed to retain the amnesia for a week. In the meantime those physicians who had arranged for the hoax sought out the senior author and related the whole plan to deceive him and to determine if hypnotic phenomena could be deliberately and successfully imitated. They also stated that they had tried to convince the actor that he had done the automatic writing but had failed in their efforts. They added that they had arranged for the actor to meet the senior author again so that the hypnotic amnesia could be removed.

Their request was met to their satisfaction and to the amazement of the actor, who summarized the entire matter by the simple statement, Well, it is obvious to me now that the best way to fake hypnosis is to go into a trance.

5. Utilizing the Patient's Negative Affects and Confusion

Most therapists are wary of a patient's negative affects, doubts, and confusion. Negative affects are usually seen as something that must be circumvented. The following is an illustration by the senior author of how negative affects can be utilized to induce trance and to facilitate therapeutic change.

A patient's misunderstandings, doubts, and uncertainties may also be utilized as the technique of induction. Exemplifying this approach are the instances of two patients, both college-trained women, one in her late 30's, the other in her early 40's. One patient expressed extreme doubt and uncertainty about the validity of hypnotic phenomena as applied to herself, but explained that her desperate need for help compelled her to try hypnosis as a remotely possible means of therapy.

The other declared her conviction that hypnosis and physiological sleep were identical and that she could not possibly go into a trance without first developing physiological sleep. This, she explained, would preclude therapy; yet she felt that hypnosis offered the only possible, however questionable, means of psychotherapy for her, provided that the hypnotherapy was so conducted as to preclude physiological sleep. That this was possible, she disbelieved completely.

Efforts at explanation were futile and served only to increase the anxiety and tension of both patients. Therefore an approach utilizing their misapprehensions was used. The technique, except for the emphasis employed, was essentially the same for both patients. Each patient was instructed that deep hypnosis would be induced. They were to cooperate in going into a deep trance by assessing, appraising, evaluating, and examining the validity and genuineness of each item of reality and each item of subjective experience that was mentioned. In so doing, the women were

to feel under obligation to discredit and reject anything that seemed at all uncertain or questionable. For the one, emphasis was placed primarily upon subjective sensations and reactions with an interspersed commentary upon reality objects. For the other, attentiveness to reality objects as proof of wakefulness was emphasized with an interspersing of suggestions for subjective responses. In this manner, there was effected for each a progressive narrowing of the field of awareness and a corresponding increase in a dependence upon and a responsiveness to the writer. It became possible to induce in each a somnambulistic trance by employing a simple eye closure progressive relaxation technique slightly paraphrased to meet the special needs of each of the two patients.

The following sample of utterances, in which the emphasis is approximately evenly divided between subjective aspects and reality objects, is offered to illustrate the actual verbalization employed.

As you sit comfortably in that chair, you can feel the weight of your arms resting on the arms of the chair. And your eyes are open and you can see the desk and there is only the ordinary blinking of the eyelids, which you may or may not notice, just as one may notice the feeling of the shoes on one's feet and then again forget about it. And you really know that you can see the bookcase and you can wonder if your unconscious has noted any particular book title. But now again you can note the feeling of the shoes on your feet as they rest on the floor, and at the same time you can become aware of the lowering of your eyelids as you direct your gaze upon the floor. And your arms are still resting their weight on the arms of the chair, and all these things are real and you can be attentive to them and sense them. And if you look at your wrist and then look at the corner of the room, perhaps you can feel or sense the change in your visual focus. Perhaps you can remember when, as a child, you may have played with the experience of looking at an object as if it were far off and then close by. And as associated memories of your childhood pass through your mind, they can range from simple memories to tired feelings because memories are real. They are things, even though abstract, as real as the chair and the desk, and the tired feeling that comes from sitting without moving, and for which one can compensate by relaxing the muscles and sensing the weight of the body, just as one can feel so vividly the weariness of the eyelids as fatigue and relaxation develop more and more. And all that has been said is real and your attention to it is real and you can feel and sense more and more as you give your attention to your hand or to your foot or the desk or your breathing or to the memory of the feeling of comfort some time when you closed your eyes to rest your gaze. And you know that dreams are real, that one sees chairs and trees and people and hears and feels various things in dreams and that visual and auditory images are as real as chairs and desks and bookcases that become visual images. In this way, with increasing frequency, the writer's utterances became simple, direct suggestions for subjective responses.

This technique of utilizing doubts and misunderstandings has been used with other patients and with experimental subjects. It is well suited to the use of hand levitation as a final development, since ideomotor activity within the visual range offers opportunity for excellent objective and subjective realities.

The above is an excellent illustration of the *interspersal approach* to introduce patients to their

own subjective responses gradually and in a manner that *focuses attention inward* for trance. Associating their inner realities with outer objects, through which they could validate their experiences; enabled them to accept the former to a greater and greater degree. The senior author then uses a series of *open-ended suggestions* in a very general discussion of sensations, feelings, memories, dreams, and visual images as a means *of indirect associative and ideodynamic focusing* to deepen their involvement with whatever subjective realities were most available to them. The utilization of doubt and misunderstanding in the example serves as an introduction to a more general understanding of negative affects as indicators of personality change.

The experience of anxiety, confusion, doubt, uncertainty, and depression is characteristic of most patients involved in a process of growth and personality change (Rossi, 1967, 1968, 1971, 1972a, 1972b, 1973; Erickson, Rossi, and Rossi, 1976). Thus while the patient is uncomfortable with these manifestations, the therapist can recognize in them the hopeful indications of a much-needed process of personality transformation that is taking place within the patient. We could even conceptualize that the typical states of depression and uncertainty with which most people enter therapy are actually spontaneous manifestations of the second and third stages (depotentiating habitual conscious sets and unconscious search) of our general paradigm of trance induction and suggestion. They are entirely normal and necessary stages in the natural process of personality growth and transformation (Rossi, 1972a). Depression and uncertainty only take pathological forms when a problem is so overwhelming that one cannot work through these uncomfortable affects on one's own. In helping patients cope with these states we can again recognize how hypnotherapy can be understood as a facilitator of natural processes inherent in psychological growth.

6. Utilizing the Patient's Symptoms

Since the patient's symptom is usually a major focus of attention, we can sometimes utilize it to facilitate trance induction and rapidly resolve the problem. With this approach we are again utilizing each patient's inner realities - dominant frames of reference and fixed belief - to induce trance and facilitate therapy. Unusually elegant examples of this approach are the following, drawn from the senior author's work in teaching dentists:

A man in his thirties became interested in hypnosis and volunteered to act as a subject for some experimental studies at a university. In the first hypnotic session he discovered that he was an excellent hypnotic subject, but lost his interest in any further experimental studies.

Several years later he decided to have hypnosis employed by his dentist, since he needed extensive dental work and feared greatly the possibility of pain.

He entered a trance state for his dentist readily, developed an excellent anesthesia of the hand upon suggestion, but failed to be able to transfer this anesthesia or even an analgesia to his mouth in any degree. Instead, he seemed to become even more sensitive orally. Efforts to develop oral anesthesia or analgesia directly also failed.

Further but unsuccessful efforts were painstakingly made by the dentist and a colleague to teach this patient by various techniques how to develop anesthesia or analgesia. He could respond in this way only in parts of the body other than the mouth. He was then brought to this writer as a special problem.

A trance state was induced readily and the patient was casually reminded of his wish for comfort in the dental chair. Thereupon, he was instructed to be attentive to the instructions given him and to execute them fully.

Suggestions were then given him that his left hand would become exceedingly sensitive to all stimuli, in fact painfully so. This hyperesthetic state would continue until he received instructions to the contrary. Throughout its duration, however, adequate care would be exercised to protect his hand from painful contacts.

The patient made a full and adequate response to these suggestions. In addition to the hyperesthesia of the hand, and *entirely without any suggestion to that effect,* he spontaneously developed an anesthesia of his mouth, permitting full dental work with no other anesthetic agent.

Even in subsequent efforts anesthesia or analgesia could not be induced directly or purposely except as a part of the hyperesthesia-anesthesia pattern peculiar to that patient. However, this is not a single instance of this type of behavior. Other comparable cases have been encountered from time to time.

Apparently, psychologically, the patient's fixed understanding was that the dental work must absolutely be associated with hyper-sensitivity. When this rigid understanding was met, dental anesthesia could be achieved in a fashion analogous to the relaxation of one muscle permitting the contraction of another.

Hypnosis had been attempted repeatedly and unsuccessfully on a dentist's wife by her husband and several of his colleagues. Each time, she stated, she became absolutely scared stiff, so I just couldn't move and then I'd start crying. I just couldn't do anything they asked. I couldn't relax, I couldn't do hand levitation. I couldn't shut my eyes; all I could do was be scared silly and cry.

A naturalistic approach employing synergism was utilized. A general summary of her situation was offered to her in the following words:

You wish to have hypnosis utilized in connection with your dental work. Your husband and his colleagues wish the same, but each time hypnosis was attempted, you have failed to go into a trance. You got scared stiff and you cried. It would really be enough just to get stiff without crying. Now you want me to treat you psychiatrically, if necessary, but I don't believe it is. Instead, I will just put you in a trance so that you can have hypnosis for your dentistry.

She replied, But I'll just get scared stiff and cry.

She was answered with, No, you will first get stiff. That is the first thing to do and do it now. Just

get more and more stiff, your arms, your legs, your body, your neck - completely stiff - even stiffer than you were with your husband.

Now close your eyes and let the lids get stiff, so stiff that you can't open them.

Her responses were most adequate.

Now the next thing you have to do is to get scared silly and then to cry. Of course, you don't want to do this, but you have to because you learned to, but don't do it just yet.

It would be so much easier to take a deep breath and relax all over and to sleep deeply.

Why don't you try this, instead of going on to getting scared silly and crying?

Her response to this alternative suggestion was immediate and remarkably good.

The next suggestion was, Of course you can continue to sleep deeper and deeper in the trance state and be relaxed and comfortable. But any time you wish, you can start to get scared stiff and silly and to cry. But maybe now that you know how to do so, you will just keep on being comfortable in the trance so that any dental or medical work you need can be done comfortably for you.

A simple posthypnotic suggestion to enable the induction of future trances was then given.

In both of these examples the therapist accepts the patient's dominant frame of reference (hypersensitivity in the first case and scared stiff in the second) and then utilizes it to introduce and facilitate therapeutic responses. He encourages the patients to do what they already know they can do and then displaces, transforms, or adds to it something they need to do. He uses questions, contingent suggestions, and associational networks to carry the patients from their well-rehearsed but maladaptive behaviors to the desired therapeutic responses. Other instructive examples that illustrate how this approach rapidly achieves therapeutic goals are as follows.

Another type of case in which this same general approach was utilized concerns a bride of a week, who desired a consummation of her marriage but developed a state of extreme panic with her legs in the scissors position at every attempt or offer of an attempt.

She entered the office with her husband, haltingly gave her story, and explained that something had to be done, since she was being threatened with an annulment. Her husband confirmed her story and added other descriptive details.

The technique used was essentially the same as that utilized in a half dozen similar instances.

She was asked if she were willing to have any reasonable procedure employed to correct her problem. Her answer was, Yes, anything except that I mustn't be touched, because I just go crazy if I'm touched. This statement her husband corroborated.

She was instructed that hypnosis would be employed. She consented hesitantly, but again demanded that no effort be made to touch her.

She was told that her husband would sit continuously in the chair on the other side of the office and that the writer would also sit beside her husband. She, however, was personally to move her chair to the far side of the room, to sit down there and watch her husband continuously. Should either he or the writer at any time leave their chairs, she was to leave the room immediately, since she was sitting next to the office door.

Then she was to sprawl out in her chair, leaning far back with her legs extended, her feet crossed, and all the muscles fully tensed. She was to look at her husband fixedly until all she could see would be him, with just a view of the writer out of the corner of her eye. Her arms were to be crossed in front of her and her fists were to be tightly clenched.

Obediently she began this task. As she did so, she was told to sleep deeper and deeper, seeing nothing but her husband and the writer. As she slept more and more deeply, she would become scared and panicky, unable to move or to do anything except to watch both and to sleep more and more deeply in the trance, in direct proportion to her panic state.

This panic state, she was instructed, would deepen her trance, and at the same time hold her rigidly immobile in the chair.

Then gradually, she was told, she would begin to feel her husband touching her intimately, caressingly, even though she would continue to see him still on the other side of the room. She was asked if she were willing to experience such sensations and she was informed that her existing body rigidity would relax just sufficiently to permit her to nod or to shake her head in reply, and that an honest answer was to be given slowly and thoughtfully.

Slowly she nodded her head affirmatively.

She was asked to note that both her husband and the writer were turning their heads away from her, because she would now begin to feel a progressively more intimate caressing of her body by her husband, until finally she felt entirely pleased, happy and relaxed.

Approximately five minutes later she addressed the writer,

Please don't look around. I'm so embarrassed. May we go home now, because I'm all right?

She was dismissed from the office and her husband was instructed to take her home and passively await developments.

Two hours later a joint telephone call was received explaining simply, Everything is all right.

A check-up telephone call a week later disclosed all to be well. Approximately 15 months later they brought their first-born in with greatest of pride.

Another example is that of an enuretic eight-year-old boy, half carried, half dragged into the office by his parents. They had previously solicited the aid of the neighbors on his behalf, and he had been prayed for publicly in church. Now he was being brought to a crazy doctor as the last resort with a promise of a hotel dinner, to be provided following the interview.

His resentment and hostility toward all were fully apparent.

The approach was made by declaring You're mad and you're going to keep right on being mad, and you think there isn't a thing you can do about it, but there is. You don't like to see a 'crazy doctor,' but you are here and.you would like to do something, but you don't know what. Your parents brought you here, made you come. Well, you can make them get out of the office. In fact, we both can - come on, let's tell them to go on out. At this point the parents were unobtrusively given a dismissal signal, to which they readily responded, to the boy's immediate, almost startled, satisfaction.

The writer then continued, But you're still mad and so am I, because they ordered me to cure your bedwetting. But they can't give me orders like they give you. But before we fix them for that - *with a slow, elaborate, attention-compelling, pointing gesture* - look at those puppies right there. I like the brown one best, but I suppose you like the black-and-white one, because its front paws are white. If you are very careful, you can pet mine, too. I like puppies, don't you?

Here the child, taken completely by surprise, readily developed a somnambulistic trance, walked over, and went through the motions of petting two puppies, one more than the other. When finally he looked up at the writer, the statement was made to him, I'm glad you're not mad at me any more and I don't think that you or I have to tell your parents anything. In fact, maybe it would serve them just right for the way they brought you here if you waited until the school year was almost over. But one thing is certain. You can just bet that after you've had a dry bed for a month, they will get you a puppy just about like little Spotty there, even if you never say a word to them about it. They've just got to. Now close your eyes, take a deep breath, sleep deeply, and wake up awful hungry.

The child did as instructed and was dismissed in the care of his parents, who had been given instructions privately.

Two weeks later he was used as a demonstration subject for a group of physicians. No therapy was done.

During the last month of the school year, the boy each morning dramatically crossed off the current calendar day.

Toward the last few days of the month he remarked cryptically to his mother, You better get ready.

On the 31 st day, his mother told him there was a surprise for him. His reply was, It better be black-and-white. At that moment his father came in with a puppy. In the boy's excited pleasure he

forgot to ask questions.

Eighteen months later the boy's bed was still continuously dry.

A careful study of these examples reveals the same pattern. In each case the senior author associates (1) what patients can do well with (2) trance behavior in which (3) they can now experience what they want in a hallucinated inner reality. This binds their real behavioral capacities to hallucinated wishes so that the wishes can become actualized. Therapeutic trance is the binding glue, the state of concentration or the medium in which fantasies and wishes are associated and bound to behavioral capacities so that what is desired can be actualized in real behavior. In hypnotherapeutic practice we are continually building bridges between what patients can do and what they want to do. This will become more and more evident in the next chapter on posthypnotic suggestion and in practically all the case studies that follow.

Exercises

1. Listen to tape recordings of your therapy sessions and determine to what degree you are utilizing the patients' own behaviors, interests, and personality characteristics to facilitate their therapeutic work.

2. As you study these recordings, consider where you might have introduced alternative remarks and suggestions that could utilize the patient's repository of life experiences and more highly developed functions to facilitate therapeutic progress. Explore those forms of indirect suggestions that fit easily within your own verbal repertory so that you can utilize them most effectively to facilitate the patient's inner searches and unconscious processes even without the formal induction of trance.

3. Study video recordings of your therapy sessions to discover those moments of rapt response attentiveness when your patient was most focused on you. How well did you utilize these moments to introduce therapeutic remarks?

4. Plan how you could use these moments of response attentiveness to introduce indirect forms of suggestions that could facilitate free association related to therapeutic issues. Some simple examples are as follows.

Do your *eyes* feel like resting and closing for a moment while your unconscious mind explores that [*whatever*]?

I want you to be quiet for a moment, and as you think that over we will see what else your unconscious mind brings up about it. And you don't have to talk until you really feel comfortable about it.

Therapists must find the combination of words that is natural to them and their patients in order to facilitate the inner search and unconscious processes in a casual and comfortable manner.

5. The above approach easily lends itself to indirect forms of trance induction. During those moments of common everyday trance when the patients may be apparently absorbed within themselves, looking out a window, staring at their hands, the floor, the ceiling, or whatever, therapists can introduce options for trance via indirect forms, such as the following:

You are absorbed in something now, and if your unconscious agrees that this is a comfortable moment for you to enter trance, you will find that your eyes will seem to close all by themselves.

Does your unconscious want those eyes to close so you can just continue as you are even more comfortably?

Just let yourself continue as you are and your body won't even have to move until your unconscious has a surprising solution to that, even though your conscious mind may not yet know what it is, exactly.

During a moment of rapt response attentiveness, when the patient's attention is focused on the therapist, trance could be introduced as follows:

I know you are not entirely aware of it, but I'm noticing something about you that indicates you may be ready to enter trance. And if your unconscious really wants to, you'll find those eyelids closing [*handlifting, or whatever*].

6. Absolutely refuse to permit yourself to use any ritualized and mechanical form of hypnotic induction until you have noticed half a dozen or more of the patient's patterns of manifest behavior, interests, abilities, inner life experiences, frames of reference, resistances, or symptoms that you can incorporate into the induction procedure. Then practice the process of integrating each patient's individuality into all the standard forms of trance induction such as eye fixation, hand levitation, and so on.

7. Study the patient's manifest behavior and symptoms to determine how they can be channeled into therapeutic responses. Practice building associative bridges between the known and possible to the unknown and desired.

8. Further study in the lore of hypnotic induction comes from many unexpected quarters. A volume on hypnotic poetry (Snyder, 1930), for example, presents the thesis that there are two basic types of poetry: hypnotic (spell-weaving) and intellectualistic. The former tends to induce trance, while the latter appeals more to the intellect. The author discusses many of the literary devices that may induce a hypnotic effect, such as (1) a perfect pattern of sound and stress, with heavy vocal stress falling at half-second intervals; (2) absence of abrupt changes or intellectual challenges; (3) vagueness of imagery, permitting each individual's personal unconscious to fill in the details; (4) fatigue for what we would call depotentiating habitual mental frameworks ; (5) the use of repetition or refrain; and (6) giving an unusually clear and direct suggestion or posthypnotic suggestion only after lulling the listener into an agreeable state with the foregoing. He goes on to point out how poetic inspiration and perhaps artistic creation in general always

involve an autohypnotic state. A careful study of the poems he presents gives the hypnotherapist a broader conception of the creative work involved in every hypnotic induction.

9. Classical studies like the above lend credence to the many current efforts to understand trance as a function of the specialized activities and interaction patterns of the left and right cerebral hemispheres (Ornstein, 1972, 1973; Hilgard and Hilgard, 1975; Bandler and Grinder, 1975; Erickson, Rossi, and Rossi, 1976; Rossi, 1977). Analyze the inductions in this and the remaining chapters of this volume for their relative appeal to the left and right hemisphere. We have introduced a number of speculations in this area in our commentaries on Case 12 in Chapter 9.

CHAPTER 4

Posthypnotic Suggestion

Traditionally, posthypnotic suggestion has been used to assess the effectiveness of trance and to reinforce a therapeutic process. It was believed that a person who receives a suggestion during trance and then carries it out afterward proves by that very fact that an effective trance was experienced. Trance was conceptualized as a blank state during which an individual was easily programmed just as one might write upon a blank slate. We now recognize that this blank slate and programming model of hypnosis is misleading for psychotherapeutic work. Individuals retain their own personality dynamics during trance. Therapeutic trance is a means of focusing attention and utilizing personality dynamics in a manner that permits unconscious processes to mediate responses that are of clinical value. In the broadest sense we can speak of posthypnotic suggestion whenever we introduce an idea during a moment of receptivity that is later actualized in behavior. That moment of receptivity can occur during a formally induced trance or during the *common everyday trance* in which attention is fixed and absorbed in a matter of great interest.

1. Associating Posthypnotic Suggestions with Behavioral Inevitabilities

The traditional approach to direct posthypnotic suggestion usually takes the form, After you awaken from trance, you will do *[or experience]* such and such. Indirect posthypnotic suggestion, by contrast, involves the use of the indirect forms of suggestion together with a number of other processes found in everyday life as well as clinical practice. The most useful of these are contingency suggestions and associational networks, whereby we tie the posthypnotic suggestion to inevitable patterns of behavior that the patient will experience in the future. These inevitable behavior patterns function as cues or vehicles for the execution of the posthypnotic suggestion. The patient's own associations, life experience, personality dynamics, and future prospects are all utilized to build the posthypnotic suggestion into the patient's natural life structure. An example from the senior author's own family life can introduce us to this concept of indirect posthypnotic suggestion in its broadest sense.

The first time an orthodontist worked on a daughter of mine I said to her, You know, all of that baling wire in your mouth is miserably uncomfortable. Why shouldn't I tell her the truth? She knew it, she was certain of it. I then said to her, That mouthful of hardware that you've got with all those rubber bands is wretchedly miserable, *and it's going to be a deuce of a job to get used to it.* Well, what did I suggest? *You will get used to it. Getting used to it* was the indirect suggestion. She heard me agreeing with her misery, but her unconscious also heard the rest of the sentence. Always know how inclusive, how comprehensive your statement is. *It is a deuce of a job to get used to it.* When you put it that way, she accepts both parts of the sentence, though she doesn't know she has accepted the second part. Then I told her, You are only a little girl now, but what

kind of a smile do you think you will have in your wedding picture? Mrs. Erickson and I kept that posthypnotic suggestion in mind for a long time until she was married. We never ever betrayed it by talking about it or telling anyone. When our daughter got married ten years later and saw her wedding pictures, she said, Daddy, this is my favorite one. Look at the smile. That was an indirect posthypnotic suggestion that worked over a period of ten years even though she could not recognize it as such. When she first went to the orthodontist, marriage was the farthest thing from her mind. She wasn't thinking of marriage at all, but she did know that women get married and there was the remote possibility that she was making the beautiful smile she would have in her wedding picture. That's what goes into the most effective posthypnotic therapeutic suggestion. When you offer a posthypnotic suggestion in the form of a hopeful prognosis to a patient, tie it to a reasonable future contingency. Marriage was a reasonable expectation for us to entertain regarding our daughter.

This example illustrates a number of basic principles for offering posthypnotic suggestion. The process was initiated, as always, by first recognizing and fully acknowledging the individual's current ongoing experience. The daughter's attention was immediately fixated when her father gave expression to the current reality by acknowledging her misery over her new orthodontic treatment. He then utilized a compound statement to tie his indirect suggestion getting used to it to her ongoing and undeniable reality. He then reinforced the suggestion even further by associating it with a reasonable future contingency, when getting used to it would be rewarded with a beautiful smile on her wedding day. Four major factors facilitating this posthypnotic suggestion can be listed as follows:

1. 1. *Fixing attention and opening a yes set* by recognizing and acknowledging current experience.

2. 2. Associating a suggestion with this current experience by way of an *indirect hypnotic form* (compound suggestion).

3. 3. *Utilizing* the person's own personality dynamics (need for a nice smile on her wedding day) as a vehicle for the suggestion.

4. 4. *Associating the suggestion with a reasonable future contingency* (her future wedding).

A number of other illustrations of posthypnotic suggestions associated with behavioral inevitabilities are as follows. The suggestion proper is in italics:

Shortly after you awaken, *I'm going to say something to you.* I'm going to arouse you *and put you back into trance.* In spite of any thinking you do, *what I say will be true.*

2. Serial Posthypnotic Suggestions

It is most instructive to realize that it is more difficult to reject two or more suggestions given together in an associational network than it is to reject a single suggestion standing alone. Consider the following example by the senior author (Erickson and Erickson, 1941), which

utilizes a five-year-old girl's interest in her favorite doll.

A five-year-old child who had never witnessed a hypnotic trance was seen alone by the hypnotist. She was placed in a chair and repeatedly told to *go to sleep,*and to *sleep very soundly,*" while holding her favorite doll. No other suggestion of any sort was given her until after she had apparently slept soundly for some time. Then she was told, as a posthypnotic suggestion, that some other day the hypnotist would ask her about her doll, whereupon she was to (a) place it in a chair, (b) sit down near it, and (c) wait for it to go to sleep. After several repetitions of these instructions, she was told to awaken and to continue her play. This three-fold form of posthypnotic suggestion was employed, since obedience to it would lead progressively to an essentially static situation for the subject. Particularly did the last item of behavior require an indefinitely prolonged and passive form of response, which could be best achieved by a continuation of the spontaneous posthypnotic trance. Several days later she was seen while at play, and a casual inquiry about her doll was made. Securing the doll from its cradle, she exhibited it proudly and then explained that the doll was tired and wanted to go to sleep, placing it as she spoke in the proper chair and sitting down quietly beside it to watch. She soon gave the appearance of being in a trance state, although her eyes were still open. When asked what she was doing, she replied, Waiting, and nodded her head agreeably when told insistently, Stay just like you are and keep on waiting. Systematic investigation, with an avoidance of any measure that might cause a purely responsive manifestation to a specific but unintentional hypnotic suggestion, led to the discovery of a wide variety of the phenomena typical of the ordinarily induced trance.

A series of subtle posthypnotic suggestions suitable for facilitating the trance training and the reinduction of trance for adults might run somewhat as follows.

1. **1. When you awaken, you will open your *eyes*. . .**

2. **2. Move and perhaps stretch a bit. . .**

3. **3. You can talk a bit about what interests you in your experience. . .**

4. **4. And forget all the rest. . .**

5. **5. Until I ask you to go back into trance. . .**

6. **6. So you can experience and remember something more.**

The first three lines of the above are a series of truisms that together form an associational network of behaviors that are inevitabilities. Since they are inevitable, they tend to initiate a yes set within the patient, who probably won't even recognize line 4 as a subtle suggestion for hypnotic amnesia. Line 5 is a fairly direct posthypnotic suggestion to reenter trance that contains an important contingency with the word until. Until means that on reentering trance the patient will remember something forgotten due to a hypnotic amnesia when he was awake. Line 6 continues the associational network binding a future trance with the current experience, and it also contains a subtle ambiguity: Will the patient merely experience and recall what was lost in the

amnesia, or will there be a new experience that will then be recalled? Will it be recalled only during trance or after trance as well? The therapist usually does not know the answers to these questions - they are a means of exploring the patient's unique system of responding. If it is found that significant amnesias are present that can be lifted by further suggestion, the therapist may decide to utilize this ability therapeutically. If new experience is forthcoming with each trance, this may become the ideal therapeutic modality for helping patients explore their inner worlds.

3. Unconscious Conditioning as Posthypnotic Suggestion

Most therapists automatically alter the tone and cadence of their voice during trance work. The patients, in turn, become automatically and usually unconsciously conditioned to experience trance in response to these vocal alterations. If the therapist adopts these vocal changes during an ordinary conversation, the patient will frequently begin to experience partial aspects of trance without quite knowing why. Since these minimal cues bypass the patient's conscious frames of reference, they are often surprisingly effective. When therapists notice these beginning manifestations of trance (e.g., eye blinking, minimal movements, blocking, some confusion, and so on), they can reinforce them with other nonverbal or verbal cues they typically use during the initial stages of trance induction. For example, when the patient is looking directly at the senior author during trance induction, he will frequently look directly at the patient's face but focus his eyes at a distance beyond. When he later does this during an ordinary conversation, the patient initially feels a bit disconcerted, then begins to experience a disorientation that can only be resolved by going into trance (Erickson, Rossi, and Rossi, 1976). At such moments the senior author may reinforce the process with a look of happy expectation and double bind questions such as the following:

I wonder just how awake you are now?

Just how much trance are you beginning to experience?

Is that a trance you're beginning to experience?

It's comfortable to just let that happen, isn't it?

You don't have to talk, do you? It's nice just to let yourself be.

When we begin to look into the matter, we realize that there are innumerable patterns of unconscious conditioning that are taking place between therapist and patient all the time. Many patients become conditioned unconsciously and automatically to begin the process of trance experience as soon as they enter the therapist's waiting room. The observant therapist need not engineer such patterns of unconscious conditioning or set them up intentionally. It is far more effective simply to observe them as they occur naturally and then to utilize them as important indicators of unconscious processes. Some patients, for example, position their bodies in certain characteristic ways during trance. Later, during an ordinary therapeutic session, the therapist may notice aspects of that trance position developing. Perhaps a head, arm, leg, hand, or finger falls

into trance position. This may be a nonverbal and unconscious body signal that the patient is reexperiencing an association to trance on some level and now needs to do trance work. When therapists recognize these body cues, they can facilitate the process with an expectant look and questions somewhat like the following:

Are you aware of what's happening to you now?

Pause for a moment. Can you sense what's taking place within you?

Do you feel you are really completely awake?

How much trance are you beginning to experience?

When the patient's body language is, indeed, a signal that trance work needs to be done, the patient will frequently use the inner search initiated by these questions to enter more deeply into trance. If the body language meant something else (such as an important association to previous trance experience that now needs to be talked about), the therapist's question provides an opportunity for it to be expressed in the awake state or perhaps in a light trance state that is difficult to distinguish from the awake state.

4. Initiated Expectations Resolved Posthypnotically

A most effective approach to posthypnotic suggestion is to initiate expectations, tensions, or patterns of behavior that can only be completed or resolved after trance is formally terminated. This approach has experimental validation in numerous studies of the Zeigarnic effect (Woodworth and Schlosberg, 1954), which demonstrate how children will return to an uncompleted task after an interruption because of the tension or disequilibrium aroused by their set for closure. In the previous section we saw how unconscious conditioning could initiate partial aspects of trance that could only be resolved by the patient actually going into trance or that could only be resolved after trance by some therapeutic behavioral change. Our five-stage paradigm of the dynamics of trance induction and suggestion in Figure 1 is particularly evident in this approach (see page 4).

The senior author frequently uses this approach with patients experiencing trance for the first time. During their first trance he will casually remark how interesting and therapeutic it can be to experience a *pleasant surprise.* He then obtains their willingness to experience a pleasant surprise after they awaken. A pleasant expectation is thus set up within the patients that can be resolved by a therapeutic shock or surprise after they awaken. This expectation is an unresolved tension that heightens their sensitivity to the therapeutic surprise that the therapist has planned. The expectation of a pleasant surprise tends to suspend patients' habitual sets and attitudes and to initiate unconscious searches and processes for the promised pleasant surprise.

After the patient has been awake for a while, the senior author guides the patient's hand and arm upward with a look of bemused expectation. The patient's arm usually remains suspended in

midair because it has been given subtle but directive tactile cues to remain so (Erickson, Rossi, and Rossi, 1976). Patients usually do not recognize these tactile cues on a conscious level, however, so they are indeed surprised at the apparently peculiar behavior of their arms. The senior author will reinforce this surprise and imply that it means the patients are entering trance in fulfillment of the posthypnotic suggestion he gave previously with remarks such as the following:

Surprising, isn't it?

Does your hand always remain up when someone touches it?

And it can be a pleasant surprise to find yourself going back into trance without any effort.

Are your eyes beginning to close?

And that hand won't go down until the other hand goes up.

The patient's surprise and puzzlement about what is happening is essentially a confusion approach to depotentiating habitual conscious sets and frameworks so that an altered state is facilitated. In the following section we will further elaborate our conception of this use of surprise and expectation to facilitate the execution of therapeutic posthypnotic suggestions.

5. Surprise as a Posthypnotic Suggestion

Surprise in a posthypnotic suggestion heightens expectancy while providing a fail-safe channel for the expression of the patient's individuality after awakening. Consider the following posthypnotic suggestion, which is most appropriately offered at the end of a period of successful trance work during which the patient is in a positive mood and experiencing a yes set.

Would you like to experience a pleasant surprise after you awaken?

A patient who responds in the affirmative to this question (by head nodding, finger signaling, verbal response, smiling, and so on) is in the following situation:

1. 1. The positive yes set of the trance work is carried over into the posthypnotic period.

2. 2. Awakening is accompanied by a sense of heightened expectation and positive motivation to experience something new.

3. 3. The patient's usual conscious sets do not know what the surprise, the new, will be. The patient's habitual conscious and limiting sets are therefore depotentiated in favor of something new that can only come from the patient's own unconscious. The suggestion for a pleasant surprise has been given in the form of a question which in itself initiates an unconscious search that may uncover and permit a new potential or another aspect of the patient's individuality to become manifest.

4. 4. The suggestion tends to be fail-safe because whatever patients experience or report after a period of successful trance work can be accepted as a pleasant surprise. If patients are happily excited, that can be a pleasant surprise. If patients are more thoughtful and appear to lapse back into body immobility as they reflect on their trance experiences, the therapist can facilitate a surprise with a suggestion such as, As you notice how quiet your body is, it may be surprising how easily your eyes can close as you go back into trance to reach a complete understanding of *that.* The therapist may not know what that is, but whatever it is can be facilitated.

5. 5. When the patient experiences a surprise in some form after trance, a therapist's final comment such as And that was a pleasant surprise, wasn't it? tends to ratify the therapeutic work that has just taken place as well as the value of trance as a valid approach to solving problems.

A number of examples illustrating this surprise form of posthypnotic suggestion will be found in the cases of this book.

Exercises

1. Associating therapeutic suggestions with behavioral inevitabilities can be practical in everyday life as well as in the consulting room. It is an approach particularly suitable for use with children provided the adult avoids sermonizing.

2. The serial posthypnotic suggestions require much thought and planning. Together with *contingency* suggestions,*associational networks,* and *double binds* they can constitute an almost impenetrable thicket for snagging practically any random association or behavioral potential the patient may have and holding it fast to the therapeutic endeavor. It becomes a fascinating exercise to interpenetrate each individual patient's *behavioral inevitabilities* with a serial pattern of suggestions so they mutually reinforce each other and, it is hoped, displace the patient's symptom.

3. Unconscious conditioning as posthypnotic suggestion requires a careful observation of patients' patterns of behavior and responsiveness whenever they come into the therapist's presence after having had a successful hypnotic experience. The therapist must then learn to follow up such careful observations with the type of questions that can facilitate inner search and deepening trance involvement. The beginner in this area may find it difficult to believe and to learn to see those spontaneous and conditioned patterns of trance behavior that develop in most patients when they meet the therapist again after a successful trance experience. Because of this it may be instructive to question every patient routinely on that next meeting in the manner suggested in this chapter. If ideomotor signaling has already been developed, it is very easy to ask within the first few minutes of that next meeting, Now if you are already beginning to experience some trance, your right hand will lift (or your eyes will close, and so on). It is important to assess the patient's state within the first few minutes of the next meeting, because after that, the initial conditioned response of trance may be rapidly extinguished, since it is displaced by the conventionalities of consciously relating to the therapeutic situation.

4. *Initiated expectations resolved posthypnotically* with *surprise* is a skill that develops along

with the use *of contingent suggestions* and *associational networks.* They can be most easily learned by expressing the simple expectation of feeling rested and comfortable upon awakening. This is generally fail-safe, since such responses almost inevitable. To these inevitabilities one can gradually add suggestions particularly suited to the patient's needs and fitting the *patient's expectations* of what should be experienced.

CHAPTER 5

Altering Sensory-Perceptual Functioning: The Problem of Pain and Comfort

Recent clinical (Lassner, 1964; Melzack and Perry, 1975) and experimental research (Hilgard and Hilgard, 1975) has validated anew centuries of experience with the hypnotic alteration of sensory-perceptual functioning for coping with pain and facilitating comfort. Hypnotherapeutic approaches have been successful in reducing pain from obvious somatic sources (such as accidental physical trauma, surgery, dentistry, obstetrics, cancer, and so on) as well as psychosomatic problems. It has been established on an experimental basis that hypnotic pain relief is due to something more than the placebo effect (McGlashan, Evans, and Orne, 1969) or anxiety reduction (Hilgard and Hilgard, 1975). Since the usefulness of hypnosis in this area has been so well established, we will focus our attention on the practical approaches that have been developed by the senior author in clinical situations.

Introduction

[*The following material was written by the senior author, and originally appeared in the Proceedings of the International Congress for Hypnosis and Psychosomatic Medicine. J. Lassner, (ed.) 1967.*]

Hypnosis is essentially a communication to a patient of ideas and understandings in such a fashion that he will be most receptive to the presented ideas and thereby motivated to explore his own body potentials for the control of his psychological and physiological responses and behavior. The average person is unaware of his capacities for accomplishment which have been learned through the experimental conditionings of his body behavior throughout his life experiences. To the average person in his thinking, pain is an immediate subjective experience, all-encompassing of his attention, distressing, and to the best of his belief and understanding, an experience uncontrollable by the person himself. Yet as a result of experiential events of his past life, there has been built up within his body, although all unrecognized, certain psychological, physiological, and neurological learnings, associations, and conditionings that render it possible for pain to be controlled and even abolished. One need only to think of extremely crucial situations of tension and anxiety to realize that the severest amount of pain vanishes when the focusing of the sufferer's awareness is compelled by other stimuli of a more immediate, intense, or life-threatening nature. From common experience, one can think of a mother suffering extremely severe pain and all-absorbed in her pain experience. Yet she forgets it without effort or intention when she sees her infant dangerously threatened or seriously hurt. One can think of men in combat who have been seriously wounded, but do not discover their injuries until later. Numerous such comparable examples are common to medical experience. Such abolition of pain occurs in daily life situations where pain is taken out of awareness by more compelling stimuli of another character. The simplest example of all is the toothache forgotten on the way to the dentist's office, or the headache lost in the suspenseful drama portrayed at the cinema. By such experiences as these in the course of a lifetime, be they major or minor, the body learns a wealth of unconscious psychological, emotional, neurological

and physiological associations and conditionings. These unconscious learnings repeatedly reinforced by additional life experiences constitute the source of the potentials that can be employed through hypnosis to control pain intentionally without resorting to drugs.

Considerations Concerning Pain

While pain is a subjective experience with certain objective manifestations and accompaniments, it is not necessarily or solely a conscious experience. It occurs without conscious awareness in states of sleep, in narcosis, and even under certain types of chemoanesthesia as evidenced by objective accompaniments and as has been demonstrated by experimental hypnotic exploration of past experiences of patients. But because pain is primarily a conscious subjective phenomenon, with all manner of unpleasant, threatening, even vitally dangerous emotional and psychological significances and meanings, an approach to the problem can be made frequently through the use of hypnosis, sometimes easily, sometimes with great difficulty. Furthermore, the extent of the pain is not necessarily a factor.

In order to make use of hypnosis in dealing with pain, one needs to look upon pain in a most analytical fashion. Pain is not a simple uncomplicated noxious stimulus. It has certain temporal, emotional, psychological, and somatic significances. It is a compelling motivational force in life's experience. It is a basic reason for seeking medical aid.

Pain is a complex, a construct, composed of past remembered pain, of present pain experience, and of anticipated pain in the future. Thus, immediate pain is augmented by past pain and enhanced by the future possibilities of pain. The immediate stimuli are only a central third of the entire experience. Nothing so much intensifies pain as the fear that it will be present on the morrow. It is likewise increased by the realization that the same or similar pain was experienced in the past, and this and the immediate pain render the future even more threatening. Conversely the realization that the present pain is a single event which will definitely come to a pleasant ending serves greatly to diminish it. Because pain is a construct, it is more readily vulnerable to hypnosis as a successful treatment modality than it would be were it simply an experience of the present.

Pain as an experience is also rendered more susceptible to hypnosis because it varies in its nature and intensity and hence, through life experiences, it acquires secondary meanings resulting in varying interpretations of the pain. Thus the patient may regard his pain in temporal terms, such as transient, recurrent, persistent, acute, or chronic. These special qualities each offer varying possibilities of hypnotic approaches.

Pain also has certain emotional attributes. It may be irritating, all-compelling, troublesome, incapacitating, threatening, intractable, or vitally dangerous. Each of these aspects leads to certain psychological frames of mind with varying ideas and associations, each offering special opportunities for hypnotic intervention.

One must further bear in mind certain other very special considerations. Long continued pain in an area of the body may result in a habit of interpreting all sensations in that area as automatically

painful. The original pain may be long since gone, but the recurrence of that pain experience has been conducive to a habit formation that may in turn lead to actual somatic disorders painful in character.

In a somewhat similar category are iatrogenic disorders and disease arising from a physician's poorly concealed concern and distress over his patient. Iatrogenic illness has a most tremendous significance because in emphasizing that there can be psychosomatic disease of iatrogenic origin, its converse cannot be overlooked: that iatrogenic health is fully as possible and of far greater importance to the patient. And since iatrogenic pain can be produced by fear, tensions, and anxiety, so can freedom from it be produced by the iatrogenic health that may be suggested hypnotically.

Pain as a protective somatic mechanism should not be disregarded as such It motivates the patient to protect the painful areas, to avoid noxious stimuli and to seek aid. But because of the subjective character of the pain, there develop psychological and emotional reactions to it that eventually result in psychomatic disturbances from unduly prolonged protective mechanisms. These psychological and emotional reactions are amenable to modification and treatment through hypnosis in such psychosomatic disturbances.

To understand pain further, one must think of it as a neuro-psychophysiological complex characterized by various understandings of tremendous significance to the sufferer. One need only ask the patient to describe his pain to hear it variously described as dull, heavy, dragging, sharp, cutting, twisting, burning, nagging, stabbing, lancinating, biting, cold, hard, grinding, throbbing, gnawing, and a wealth of other such adjectival terms.

These various descriptive interpretations of the pain experience are of marked importance in the hypnotic approach to the patient. The patient who interprets his subjective pain experience in terms of various qualities of differing sensations is thereby offering a multitude of opportunities to the hypnotherapist to deal with the pain. To consider a total approach is possible. But more feasible is the utilization of hypnosis in relation first to minor aspects of the total pain complex and then to its increasingly severe and distressing qualities. Thus, minor successes will lay a foundation for major successes in relation to the more distressing attributes of the neuro-psycho-physiological complex of pain, and the understanding and cooperation of the patient for hypnotic intervention are more readily elicited. Additionally, any hypnotic alteration of any single interpretive quality of the pain sensation serves to effect an alteration of the total pain complex.

Another important consideration in the comprehension of the pain complex is the recognition of the experiential significances of various attributes or qualities of subjective sensation, and their differing relationships in such matters as remembered pain, past pain, immediate pain, enduring pain, transient pain, recurrent pain, enduring persistent pain, intractable pain, unbearable pain, threatening pain, etc. In applying these considerations to varying subjective elements of the pain complex, hypnotic intervention is greatly accelerated. Such analysis offers greater opportunity for hypnotic intervention at a more comprehensive level. It becomes easier to communicate ideas and understandings through hypnosis and to elicit the receptiveness and responsiveness so vital in

securing good response to hypnotic intervention. It is also important to acknowledge adequately the unrecognized force of the human emotional need to demand the immediate abolition of pain, both by the patient himself and by those attending him.

Hypnotic Procedures in Pain Control

The hypnotic procedures for handling pain are numerous in character. The first of these most commonly practiced but frequently not genuinely applicable is the use of *direct hypnotic suggestion for total abolition of pain.* With a limited number of patients, this is a most effective procedure. But too often it fails, serving to discourage the patient and to prevent further use of hypnosis in the patient's treatment. Also, its effects, while they may be good, are sometimes too limited in duration which may limit the effectiveness of the *permissive indirect hypnotic abolition of pain.* This is often much more effective, and although essentially similar in character to direct suggestion, it is worded and offered in a fashion much more conducive to patient receptiveness and responsiveness.

A third procedure for hypnotic control of pain is the utilization of *amnesia.* In everyday life we see the forgetting of pain whenever more threatening or absorbing experiences secure the attention of the sufferer. An example is the instance already cited of the mother enduring extreme pain, seeing her infant seriously injured, forgetting her own pain in the anxious fears about her child. Then of quite opposite psychological character is the forgetting of painful arthritis, headache or toothache while watching an all-absorbing suspenseful drama on a cinema screen.

But amnesia in relationship to pain can be applied hypnotically in a great variety of ways. Thus one may employ partial, selective, or complete amnesias in relationship to selected subjective qualities and attributes of sensation in the pain complex as described by the patient, as well as to the total pain experience.

A fourth hypnotic procedure is the employment of *hypnotic analgesia,* which may be partial, complete, or selective. Thus, one may add to the patient's pain experience a certain feeling of numbness without a loss of tactile or pressure sensations. The entire pain experience then becomes modified and different and gives the patient a sense of relief and satisfaction, even if the analgesia is not complete. The sensory modifications introduced into the patient's subjective experience by such sensations as numbness, an increase of warmth and heaviness, relaxation, etc. serve to intensify the hypnotic analgesia to an increasingly complete degree.

Hypnotic anesthesia is a fifth method in treating pain. This is often difficult and may sometimes be accomplished directly, but is more often best accomplished indirectly by the building of psychological and emotional situations that are contradictory to the experience of the pain and which serve to establish an anesthetic reaction to be continued by post-hypnotic suggestion.

A sixth hypnotic procedure useful in handling pain concerns the matter of suggestion to effect the *hypnotic replacement or substitution of sensations.* For example, one cancer patient suffering intolerable pain responded most remarkably to the suggestion of an incredibly annoying itch on

the sole of her foot. Her body weakness occasioned by the carcinomatosis and hence inability to scratch the itch rendered this psychogenic pruritis all-absorbing of her attention. Then hypnotically, feelings of warmth, of coolness, of heaviness and of numbness were systematically induced for various parts of her body where she suffered pain. And the final measure was the suggestion of an endurable but highly unpleasant and annoying minor burning-itching sensation at the site of her mastectomy. This procedure of replacement substitution sufficed for the patient's last six months of her life. The itch of the sole of her foot gradually disappeared but the annoying burning-itching sensation at the site of her mastectomy persisted.

Hypnotic displacement of pain is a seventh procedure. This is the employment of a suggested displacement of the pain from one area of the body to another. This can be well illustrated by the instance of a man dying from prostatic metastalic carcinomatosis and suffering with intractable pain in both states of drug narcosis and deep hypnosis, particularly abdominal pain. He was medically trained and understood the concept of referred and displaced pain. In the hypnotic trance he readily accepted the idea that, while the intractable pain in his abdomen was the pain that would actually destroy him, he could readily agree that equal pain in his left hand could be entirely endurable, since in that location it would not have its threatening significances. He accepted the idea of referral of his abdominal pain to his left hand, and thus remained free of body pain, becoming accustomed instead to the severe pain in his left hand which he protected carefully. This hand pain did not interfere in any way with his family life during the remaining three months of his life. It was disclosed that the displaced pain to the left hand often gradually diminished, but the pain would increase upon incautious inquiry.

This possibility of displacement of pain also permits a displacement of various attributes of the pain that cannot otherwise be controlled. By this measure these otherwise uncontrollable attributes become greatly diminished. Thus the total complex of pain becomes greatly modified and made more amenable to hypnotic intervention.

Hypnotic dissociation can be employed for pain control, and the usual most effective methods are those *of time and body disorientation.* The patient with pain intractable to both drugs and hypnosis can be hypnotically reoriented in time to the earlier stages of his illness when the pain was of minor consideration. And the disorientation of that time characteristic of the pain can be allowed to remain as a posthypnotic continuation through the waking state. Thus the patient still has his intractable pain, but it has been rendered into a minor consideration as it had been in its original stages.

One may sometimes successfully reorient the patient with intractable pain to a time predating his illness and, by posthypnotic suggestion, effect a restoration of the normal sensations existing before his illness. However, although intractable pain often prevents this as a total result, pleasant feelings predating the illness may be projected into the present to nullify some of the subjective qualities of his pain complex. Sometimes this effects a major reduction in pain.

In the matter of *body disorientation,* the patient is hypnotically dissociated and induced to experience himself as apart from his body. Thus one woman with the onset of unendurable pain, in response to posthypnotic suggestions, would develop a trance state and experience herself as

being in another room while her suffering body remained in her sickbed. This patient explained to the author when he made a bedside call, Just before you arrived, I developed another horrible attack of pain. So I went into a trance, got into my wheel chair, came out into the living room to watch a television program, and I left my suffering body in the bedroom. And she pleasantly and happily told about the fantasized television program she was watching. Another such patient remarked to her surgeon, You know very well, Doctor, that I always faint when you start changing my dressings because I can't endure the pain, so if you don't mind I will go into a hypnotic trance and take my head and feet and go into the solarium and leave my body here for you to work on. The patient further explained, I took a position in the solarium where I could see him (the surgeon) bending over my body but I could not see what he was doing. Then I looked out the window and when I looked back he was gone, so I took my head and feet and went back and joined my body and felt very comfortable. This particular patient had been trained in hypnosis by the author many years previously, had subsequently learned autohypnosis, and thereafter induced her own autohypnotic trance by the phrase, You know very well, Doctor. This was a phrase that she could employ verbally or mentally at any time and immediately go into a trance for the psychological-emotional experience of being elsewhere, away from her painful body, there to enjoy herself and remain until it was safe to return to her body. In this trance state which she protected very well from the awareness of others, she would visit with her relatives, but experience them as with her in this new setting while not betraying that personal orientation.

A ninth hypnotic procedure in controlling body pain, which is very similar to replacement or substitution of sensations is *hypnotic reinterpretution of pain experience.* By this is meant the reinterpreting for the patient in hypnosis of a dragging, gnawing, heavy pain into a feeling of weakness, of profound inertia, and then as relaxation with the warmth and comfort that accompanies deep muscular relaxation. Stabbing, lancinating and biting pains may sometimes be reinterpreted as a sudden startle reaction, disturbing in character, but momentary in duration and not painful. Throbbing, nagging, grinding pain has been successfully reinterpreted as the unpleasant but not distressing experience of the rolling sensations of a boat during a storm, or even as the throbbing that one so often experiences from a minor cut on the fingertip with no greater distressing characteristics. Full awareness of how the patient experiences his pain is required for an adequate hypnotic reinterpretation of the pain sensation.

Hypnotic time distortion, first described by Cooper and then later developed by Cooper and Erickson (Cooper, L., and Erickson, M., *Time Distortion in Hypnosis,* Baltimore: Williams and Wilkins, 1959) is often a most useful hypnotic measure in pain control. An excellent example is that of the patient with intractable attacks of lancinating pain which occurred approximately every twenty to thirty minutes, night and day, and which lasted from five to ten minutes. Between the attacks the patient's frame of mind was essentially one of fearful dread of the next attack. By employing hypnosis and teaching him time distortion, it was possible to employ, as is usually the case in every pain patient, a combination of several of the measures described here. In the trance state, the patient was taught to develop an amnesia for all past attacks of pain. He was then taught time distortion so that he could experience the five to ten minute pain episodes in ten to twenty seconds. He was given posthypnotic suggestions to the effect that each attack would come as a complete surprise to him, that when the attack occurred he would develop a trance state often to twenty seconds duration, experience all of the pain attack, and then come out of the trance with

no awareness that he had been in a trance or that he had experienced pain. Thus the patient, in talking to his family, would suddenly and obviously go into the trance state with a scream of pain, and perhaps ten seconds later come out of the trance state, look confused for a moment, and then continue his interrupted sentence.

An eleventh hypnotic procedure is that of offering *hypnotic suggestions effecting a diminution of pain,* - not a complete removal of the pain, since it had become apparent that the patient was not going to be fully responsive. This diminution is usually best brought about by suggesting to the hypnotized patient that his pain is going to diminish imperceptibly hour after hour without his awareness that it is diminishing until perhaps several days have passed. He will then become aware of all pain or of special pain qualities. By suggesting that the diminution occur imperceptibly, the patient cannot refuse the suggestion. His state of emotional hopefulness, despite his emotional despair, leads him to anticipate that in a few days there may be some diminution; particularly that there may be even a marked diminution of certain attributes of his pain experience. This, in itself, serves as an autosuggestion to the patient. In certain instances, however, the patient is told that the diminution will be to a very minor degree. One can emphasize this by Utilizing the ploy that a one percent diminution of his pain would not be noticeable, nor would a 2 percent, nor a 3 percent, nor a 4 percent, nor a 5 percent diminution, but that such an amount would nevertheless be a diminution. One can continue the ploy by stating that a 5 percent diminution the first day and an additional 2 percent the next day still would not be perceptible. And if on the third day there occurred a 3 percent diminution, this, too, would be imperceptible. But it would total a 10 percent diminution of the original pain. This same series of suggestions can be continued to a reduction of pain to 80 percent of its original intensity, then to 70 percent, 50 percent, 40 percent, and sometimes even down to 10 percent. In this way the patient may be led progressively into an even greater control of his pain.

However, in all hypnotic procedures for the control of pain one bears in mind the greater feasibility and acceptability to the patient of indirect as compared with direct hypnotic suggestions, and the need to approach the problem by indirect and permissive measures as well as by employing a combination of the various methodological procedures described above.

Summary

Pain as a subjective experience is perhaps the most significant factor in causing people to seek medical aid. Treatment of pain as usually viewed by both physician and patient is primarily a matter of elimination or abolition of the sensation. Yet pain in itself may be serving certain useful purposes to the individual. It constitutes a warning, a persistent warning of the need for help. It brings about physical restriction of activity, thus frequently benefiting the sufferer. It instigates physiological changes of a healing nature in the body. Hence, pain is not just an undesirable sensation to be abolished, but rather an experience to be so handled that the sufferer benefits. This may be done in a variety of ways, but there is a tendency to overlook the wealth of psycho-neuro-physiological significances pain has for the patient. Pain is a complex, a construct composed of a great diversity of subjective interpretative and experiential values for the patient. Pain, during life's experience, serves to establish body learnings, associations, and conditionings

that constitute a source of body potentials permitting the use of hypnosis for the study and control of pain. Hypnotic procedures, singly or in combination, for major or minor effects in the control of pain described for their application are: Direct Hypnotic Suggestion for Total Abolition of Pain; Permissive Indirect Hypnotic Abolition of Pain; Amnesia; Hypnotic Analgesia; Hypnotic Anesthesia; Hypnotic Replacement or Substitution of Sensations; Hypnotic Displacement of Pain; Hypnotic Dissociation; Reinterpretation of Pain Experience; Hypnotic Suggestions Effecting a Diminution of Pain.

Case 1 A Conversational Approach to Altering Sensory-Perceptual Functioning: Phantom Limb Pain and Tinnitus.

Our first case illustrates the simultaneous therapy of a married couple who presented two apparently different symptoms: The seventy-two-year-old husband (H) suffered from phantom limb pain; his seventy-five-year-old wife (W) was bothered by tinnitus, an unpleasant ringing in her ears that had bothered her constantly for years. The husband had seen Erickson (E) for the first time a week earlier and had experienced some relief. Erickson and Rossi (R) then asked him and his wife to join them for a hypnotherapeutic session that would be free of charge if they were willing to be tape-recorded for possible publication. This offer was gratefully received by them. The *rapport* that Erickson had already established with the husband was now enhanced since they both appreciated the therapy and special consideration they were receiving. They entered the therapy room wide-eyed with hopeful *expectation* and immediately focused their entire attention on Erickson. Their *response attentiveness* was already at an ideal level. As can be seen from the transcript, they are both very respectful, cooperative, and eager for help. They have no evident misconceptions or resistances to hypnosis, so Erickson can introduce them immediately to the concept of learning to alter their own sensory-perceptual functioning for relief of their symptoms. He does this with a rather relaxed and seemingly casual conversation wherein he tells them interesting stories about his youth and the fascinating ways people can learn to regulate and alter many of their bodily processes. This enjoyable talk is actually a careful preparation during which Erickson is *structuring frames of reference* about their abilities to alter their own sensory-perceptual processes. He is preparing them for the relatively brief period of therapeutic trance that will follow, when he will offer suggestions to help evoke their repertory of sensory-perceptual skills that can be utilized for ameliorating their symptoms.

A Conversational Approach to Altering Sensory-Perceptual Functioning: Structuring a Therapeutic Frame of Reference

W: Well this phantom pain-if we could lick that, it would be wonderful.

E: All right. Now I am going to give you a story so that you can understand better. We learn things in a very unusual way, a way that we don't know about. In my first year of college I happened to come across that summer a boiler factory. The crews were working on twelve boilers at the same time, and it was three shifts of workmen. And those

pneumatic hammers were pounding away, driving rivets into the boilers. I heard that noise and I wanted to find out what it was. On learning that it was a boiler factory, I went in and I couldn't hear anybody talking. I could see the various employees were conversing. I could see the foreman's lips moving, but I couldn't hear what he said to me. He heard what I said. I had him come outside so I could talk to him. And I asked him for permission to roll up in my blanket and sleep on the floor for one night. He thought there was something wrong with me. I explained that I was a premedic student and that I was interested in learning processes. And he agreed that I could roll up in my blanket and sleep on the floor. He explained to all the men and left an explanation for the succeeding shift of men. The next morning I awakened. I could hear the workmen talking about that damn fool kid. What in hell was he sleeping on the floor there for? What did he think he could learn? ***During my sleep that night I blotted out all that horrible noise of the twelve or more pneumatic hammers and I could hear voices. I knew that it was possible to learn to hear only certain sounds if you tune your ears properly. You have ringing in your ears, but you haven't thought of tuning them so that you don't hear the ringing.***

Since *rapport*and *response attentiveness* were already established with this couple, the senior author was able to immediately *structure a therapeutic frame of reference* with this story about how the unconscious automatically learns to adjust our sensory-perceptual functioning in an adaptive manner even when we are asleep. He does not tell them in a direct and intellectual manner that they will have to learn to alter their sensory-perceptual functioning. If he did, they might find some issue to argue about or, as so commonly happens with patients who have experienced a great deal of failure, they might immediately plead that they could not alter their functioning; they would not know how to do it, or would not be able to believe that it could happen to them. His stories about himself and the illustrations he continues to present are all established facts that together structure the basic frame of reference which the couple will need for their therapeutic work. He continues now in a rather humorous vein.

Interspersing Therapeutic Suggestions

E: ***Now this matter of tuning yourself.*** **I spent three months on the Mississippi River and I got invited into a home and I felt so cooped up after being out in the open. Getting into a room, everywhere you look, your looks come to an end. When you read the old-time sailing stories, where you look to the end of the earth with nothing interfering. And the old-time stories of sailors' claustrophobic reactions. Fear of closed spaces.**

Also when I got back from that canoe trip . . . have you ever tried to sleep on a soft bed? You are miserable. I had learned to sleep on theground, in brush piles. inside the canoe. My ribs fighting with canoe ribs.

When I got home and had a mattress, that was torture. The Indians did not like, in the early days, the white man's bed. They wanted the ground to sleep on. They ***wanted comfort. Just nothing but sheer comfort.***

On the Tribal Eye program on KAET. Those nomads from Iran. How can they dress with

all those petticoats? And be comfortable in the hot sun on those desert plains? ***And you can get so used to the ringing in your ears that you don't hear it.***

I grew up on the farm. I had to be away from the farm for quite some years before I learned the barn smell on your hands when you live on the farm. I never smelled it when I was on the farm. I had to be away from it for a long time before I discovered the barn smell.

R: I guess that is why it is so hard to convince someone who doesn't wash often enough that he has to wash more often. He doesn't smell himself!

E: I can tell you a funny story about that. One year the boy in the next room at the rooming house had a fellow roomer who came from South Dakota. And Hebbie came from Milwaukee. And Hebbie told Lester, ' 'You stink, go take a bath.'' It was the latter part of September and Lester said, But I took a bath last July. I won't need one until at least Thanksgiving Day. But he really stunk, and Hebbie said, You are going to take a bath if I have to put you in the tub myself. ***What people don't know, that they can lose that pain and they don't know they can lose that ringing in the ears.*** **When I discovered that that barn smell had come back, I could really smell it. I wondered how long it would take me that day to lose it? Then by midafternoon I couldn't smell it. All of us grow up** ***believing that when you have pain, you must pay attention to it. And believing when you have ringing of the ears that you must keep on hearing it.***

As the senior author continues with one illustration after another, he gradually begins to intersperse therapeutic suggestion (in *italics)* about how she can learn to *tune out* her ringing and he can *lose* his pain. Because these suggestions are interspersed within a network of stories they are interested in hearing, the patients tend to accept the suggestions (without even realizing that therapy is taking place) particularly since the senior author moves quickly on to another interesting anecdote before they can protest or reject or even think about the interspersed therapeutic suggestions..

Although Erickson has not made any effort to induce a trance in a formal manner, it is evident that his stories are so absorbing the couple's attention that they are actually a bit entranced.

They simply sit quietly with their eyes fixed upon him. They are obviously relaxed and oblivious to anything else that might be going on around them. They are exhibiting a state of *response attentiveness* that is ideal, for the receptivity will enhance their experience of therapeutic trance.

Accepting the Therapeutic Frame of Reference

E: Now, the pain you feel, where? Where do you feel the pain?

H: Right at the present time, in my foot.

E: Yes.

W: Where there is no foot.

H: Where there is no foot.

E: All right, I had a friend named John. He was a psychiatrist, and we were visiting. He reached down and scratched his ankle. I said, John, that really itches, doesn't it? And he said, Yes. We both knew it was a wooden leg.

H: My understanding is that when I was in the hospital there was a double amputee over there. I saw him twice. I had seen him at the hospital and I had seen him over at Good Sam's taking therapy. But the nurse taking care of him at St. Joseph, when he said his foot itched, she'd reach down and scratch his sheet and relieve it.

W: Where his foot would have been?

H: Where his foot would have been! She would scratch the sheet down there and said that it would relieve it.

After listening to the senior author recount his anecdotes and stories of the relativity of sensations and phantom limb pain, the husband now shows evidence of accepting and joining this therapeutic frame of reference by telling his own anecdote about it. He goes further as he now begins to make an emphatic effort to convince his own wife when she asks a doubting question.

Creating Expectancy by Introducing New Response Possibilities: Phantom Pleasure

E: Like I asked my friend John, So you scratched it, how does your foot feel now? He said, Good. That nurse was very wise. *Because you can have good feelings in the foot.* Not just painful ones.

H: Oh, I hope so, Doctor.

E: That's what is overlooked in these amputees. They forget that they can also have good feelings.

H: I was at the leg man's yesterday. My leg wouldn't unlock. I went to him. He had three different rooms. No, two different besides mine. In each one they were talking about what can we do for this phantom pain that he got. He said, It is driving me nuts. Of course, I never opened my mouth, because I was in another room. I didn't say I was out here or nothing. I knew I had had relief from what you done before.

E: All right. Now I want to have you two recorded so that Dr. Rossi could include it in the book. Now if you have phantom pain in a limb, *you may also have phantom good feelings. And they are delightful.*

H: That I haven't had yet.

E: That's right.

H: That I haven't had yet.

E: But you can learn them!

Since the husband obviously accepted the therapeutic frame of reference, Erickson immediately pressed on with a further suggestion of how he can cope with phantom limb pain by converting it to phantom limb pleasure. Erickson introduces pleasure only tentatively as a possibility at this point. The patient certainly is not yet ready for a direct suggestion about experiencing pleasure. When the husband admits he has not experienced pleasure, Erickson utilizes the learning frame of reference he has so carefully developed earlier with his stories. With this background of illustrations he can now confidently say to the husband, But you can learn them! Since the husband enjoyed and accepted all those anecdotes about learning to change sensory-perceptual experiences, he cannot now reject Erickson's direct suggestion about his eventually learning also.

Thus, even before trance experience is formally begun in this session, Erickson has structured the basic therapeutic frame of reference for the husband in such a way that he finds himself accepting it. It is now only a question of when he will begin to utilize that therapeutic frame. When the husband responds with, Oh, I hope so, doctor, we can recognize that a high degree of *expectancy for a therapeutic response is being created.*

Autohypnosis: Therapy by Geometric Progression

H: But I will say this, that in the afternoon I will lay down for an hour and I just go into a complete trance and I don't think of nothing.

W: After he [H] came to you [E].

H: After I come from you, I think of nothing. And it is not a sleep. I know I am not asleep. But I am in a trance. I have no pain whatsoever. And when I get up, I feel so much different.

E: All right. ***And your next problem is learning to keep that good feeling a second longer.*** **And two seconds longer. Then four seconds longer. And six! And eight!**

H: You know, doctor, you told me, the best that I can recall, when I was over here the other time, start in at twenty and count backward. That is what I do when I lay down. Now I don't recall all of what you said, but I remember something you said about nine, six, and three. I remember that before I went into this trance or whatever you might call it. And I try to think of those numbers each time that I lay down and try to count from twenty backward. I emphasize on that nine, six, and three. But as I say, I am not asleep. I can lay there. It seems to me as though I can lay there forever. Two or three hours, but I am not

asleep, I am in a trance. My eyes are closed. I hear nothing. My wife can come in the room and I don't hear her. But after a certain length of time, I'm wide awake.

E: And we had it directly from his lips.

R: Yes. Isn't that beautiful. A good description of trance.

H: That's just the way it is. It has been with me, and I have only been out here since last Monday, wasn't it?

W: I think so.

The husband now acknowledges the senior author's belief in the ability to learn to alter phantom pain sensations by describing his experiences of autohypnosis, which he learned just a week ago. Already he has learned to eliminate pain during the autohypnotic trance. Erickson seizes upon that and seeks to extend comfort for longer periods - second by second. This is one of his favorite therapeutic approaches - geometric progression. It is usually quite easy for patients to experience relief from their symptoms during autohypnosis. The problem is when they come out of it. The senior author then asks them if they can extend their symptom-free condition for one second after trance today. Then double it to two seconds tomorrow. And double it again to four seconds the day after. If they continue doubling the amount of symptom-free time in this geometric progression every day, in eighteen days they will be extending it for more than twenty-four hours.

An interesting aspect of the husband's description of his autohypnotic trance experience is his emphasis on 9, 6, and 3 when he awakens. Erickson frequently trains people to go into trance by counting from 1 to 20 and to awaken by counting backward. He had no conscious awareness on this occasion of having said or done anything special with the numbers nine, six, and three. This appears to be a purely subjective, idiosyncratic response on the husband's part. It is accepted nonetheless as a valid and worthwhile part of his personal experience of trance. Precisely because it is a purely subjective experience, it is perhaps even more valuable in facilitating his trance experience, because in some way or other it utilizes his own internal associations in a constructive manner.

The husband and wife go on now to discuss their caring relationship for each other. Erickson utilizes this to talk about his daughter Roxanna who is studying to be a nurse. The point of his introducing Roxanna soon reveals itself as yet another example of someone who has done well in life because she was willing to learn.

Facilitating the Therapeutic Frame of Reference: Open-Ended Suggestions

H: Of course my wife is very concerned over me. She takes care of me just like she does a baby, you might say. I am concerned over her because she is concerned over me. So. But as she said as we crossed these steps out here a while ago, We are going to make it, we are going to make it together.

E: Well. I tell my wife not to be concerned about me. I'm just in a wheelchair. That's all! I want to put her energy toward enjoying things.

H: She used to be very active. She used to swim. She didn't learn to swim till she was fifty years old.

W: Fifty-five.

H: Fifty-five. She swam five miles without stopping. Won a woman's trophy at the YWCA. She works with the retarded children. And stuff like that. That is what I want her to get back into, instead of thinking that she has to stay at home to take care of me.

W: When he gets able, I will.

H: Well, I think I am able enough for you to start it. I really do.

W: When I worked with a little retarded child, it did me more good than it did him.

E: Where, in Sun Valley? W: A little boy on the piano.

H: My wife would play a piece, and he would get down and look all round that piano and everything. She would put it on her cassette. When she would get through, she would say, Now Kenny, you play it.

W: The piano would be in the auditorium. And I would say, Now Kenny, just pretend like you are playing before a crowd of people. Close your eyes and smile. He would close his eyes and smile. Then sit there and play.

E: All right.

H: She enjoyed it and I enjoyed her doing that type of work. It done her more good than it done the child. It really did.

E: [Gives a detailed account of how his daughter put herself through many work and training experiences before she was certain she wanted to become a nurse.] Now my daughter was willing to learn.

W: Right!

E: Your husband knows how he can feel pain in that foot. He saw another patient learn how to get comfortable from a nurse scratching a sheet.

H: That he did.

E: That's correct. My friend John said, It feels so good when I scratch my wooden leg. He

had his Ph.D. and his M.D.

R: Scratching a wooden leg!

W: Sounds fantastic, doesn't it?

R: Yes, really! The power of the mind!

E: A true story. John was marvelous. And I discussed with him the importance *of having nice feelings in your wooden foot, your wooden knee.*

H: You discussed what, now?

E: I discussed with him *the importance of having good feelings in the wooden foot, the wooden knee, the wooden leg. Feeling it to be warm. Cool. Rested.* But most patients with phantom limb pain just think of only the pain. And if you can have phantom *pain, you can have phantom pleasure.*

H: Oh, boy!

W: It sounds good, dear, I never thought of it.

H;. Yeah, I'll take the pleasure.

R: All right, sir!

E: And you saw someone else demonstrate scratching your sheet. It felt good. And that nurse was very successful.

With these remarks the senior author reinforces the therapeutic frame of reference with further examples of altering phantom pain to warmth, coolness, rest, and the possibility of pleasure. He is introducing many therapeutic possibilities in an open-ended manner. At this point Erickson still does not know which of these response possibilities the husband's system will be able to utilize. He will allow the husband's own individuality to choose between them. This is a basic principle of therapeutic suggestion: *The therapist offers possibilities, and the patient's unconscious chooses and mediates the actual response modality of therapeutic change in keeping with his own capabilities.* Therapeutic suggestion cannot impose something foreign on patients; it can only help patients to evoke and to utilize what is already present within their own response repertory.

The conversation now shifts to visiting nurses, their medical doctor, and the heart pacemaker that the husband has. The senior author utilizes this latter topic to give further illustration of our ability to alter physiological functions such as heart rate and blood pressure.

Further Structuring of the Therapeutic Frame of Reference: Altering Heart Rate and Blood Pressure

E: All right. Now a doctor from Michigan and one from Pennsylvania were visiting me, and my daughter Roxanna was then taking blood pressures all over the city. She asked them if she could take their blood pressure. And they both said, Do you want it as it is normally, or would you like it ten points lower or ten points higher? She said, All three. So she got the normal reading and then they told her she would find out whether it is lower or higher. She found out.

W: How could they control it?

E: Blood pressure changes according to where the blood is. When you go to sleep at night, your blood drains out of your brain and into a plexus, a collection of blood vessels in the abdomen. You wake up and blood pressure is increased and shoves blood back into your brain.

H: That is what I have to do every morning, first thing I go in and she fixes me a cup of coffee. I take my pulse and it averages between seventy and seventy-one every morning. They told me if it got below sixty-nine to call them. My granddaughter lives up in Flagstaff, and I haven't been up there since they bought a business and are buying a home. I asked my doctor if I could go up there. He said, Well go up there for an hour and a half or two hours, but be very careful with your heart condition and things. Well, I went over there an hour and half, and it was hard to breathe from there on down. I could only breathe from here on up, you might say. So they said let's get him to the emergency hospital, and I said no, I didn't want to go to an emergency hospital. I wanted to go home. So after we hit around 3,500-4,000-foot level, it began to come back. It was down to fifty-nine. It was down to fifty-nine. Then it came up a little bit when I came over Sunset Point. That is 5,000-foot altitude. I found I can't go any higher than that altitude.

W: I never feel it.

E: Now my friends have experimented, and they can raise the heartbeat for 5,000 feet or 10,000 feet voluntarily.

W: Really? Imagine that.

E: And I wanted your husband to realize that *there is a lot he can do for himself.* A friend of mine said, I have never been able to blush in my whole life. Will you help me to learn to blush? I told him I would. I often dropped by there in various hours of the day, and his wife was my secretary. One evening I dropped in when they were at the table. We exchanged news and all of a sudden I said, Bill! What are you blushing about? He turned bright red. Half an hour later he said, Please turn it off. My face is still burning.

W: Sounds impossible, doesn't it?

E: But it isn't! Have you ever lived where it is cold weather?

W: Yes.

E: Well, you sit in a warm room and go into the cold, what happens? Your nose gets hard.

W: A complete change.

E: Your blood vessels in your face have been turning on and off. You learned that in the wintertime. Yes. You have got that learning. Ordinarily people don't use it. But this Michigan doctor and Pennsylvania doctor had worked with me, and then they started using the thing that they already knew but had never thought of using. You run, your blood pressure goes up. You rest, your blood pressure goes down. Your heart rate can go up, it can go down. *You can think about increasing your heart rate and you can speed it up. And you can do it comfortably and easily. So long as you know that you can do it.* And that is why I am having you here today. Just to give you more information about yourself.

In these further examples, the senior author gives more suggestions about controlling physiological functioning. He deals with the important problem of H's coping with minor variations in the functioning of his pacemaker. Such variations, when they are not expected and understood, can panic patients and worsen their condition. Whenever he deals with symptom problems, Erickson always casually mentions how a momentary or temporary return of a symptom can be a normal signal about the body's functioning rather than the persistent return of the symptom or illness per se. This forestalls many lapses back into illness. In his example of blushing Erickson gives a humorous illustration of his surprise approach to altering physiological functioning (Erickson, 1964; Rossi, 1973; Erickson, Rossi, and Rossi, 1976).

Trance Induction: Modeling Trance Behavior

E: [To H] Now I would like to have you go into a trance. [To W] Watch him now.

Pause as the husband adjusts his body comfortably, closes his eyes, and goes into a trance. Just at this critical moment a youth from the street knocks loudly on the door of Erickson's office, opens it, and boldly invites us to attend his Baptist church. All of us are startled by his sudden intrusion except for H, who shows absolutely no reaction as he continues with his trance. In asking the wife who has never experienced trance to watch her husband enter trance, Erickson is using one of his favorite approaches to trance training. He simply has the new subject watch another more experienced subject go into trance.

Facilitating Normal Variations in Physiological Functioning

E: I've seen variations in blood pressure already. Now he wants to keep the heart rate about seventy. But it is all right when sleeping for his heart rate to be less than seventy. In the waking state, yes, seventy is all right, seventy-two is all right. If it drops below sixty-nine in his sleep, that's all right too. If it drops to sixty-eight, that is all right too. There is no occasion for alarm because the heart normally slows during sleep, and I don't want him to keep his heart at the waking level of beating. Now the heart can slow down in

different ways. It can beat the same number of times per minute, but beat so it does not push as large a volume of fluid. It can beat the same number of times but beat less blood through the veins. He needs less blood circulating in his body when he is asleep, so the heart does not need to beat as hard as when he is awake. ***And he can regulate that.*** **Now as you see, his entire body is at rest, and in the trance he can let one arm be awake while the rest of his body is in a trance. He can let his right leg go into a trance while the rest of his body is awake.**

The senior author immediately notes a variation in H's blood pressure as he enters trance from the variations in his pulse that can be seen (usually some place on the temple, throat, arm, etc) by therapists who have trained themselves to look for it. His mentioning this variation tends to ratify trance as an altered state and lead into therapeutic suggestions about the normal variations to be expected in his heart rate. Note the easy manner with which the senior author is open-ended in his suggestion to permit the heart to vary in its functioning in any way that is necessary (number of beats, volume of fluid). In mentioning how one part of the body can be awake and move while the rest of the body is immobile in trance, he is indirectly suggesting how patients can spontaneously shift for comfort now and then without feeling they are thereby waking up.

Dissociation Training

E: [To W] He said that he could be in a trance and you could come in and he would not know it. And Dr. Rossi knows that in a trance state I have a subject here, oh, she and I are here, but he isn't. She can't see him, she can't hear him, but she can see and hear me. In other words, human beings can isolate various parts of the body.

With these remarks addressed to the wife Erickson is giving indirect suggestions to the husband for learning how to dissociate one's attention or a part of the body. Such dissociations are useful in facilitating trance depth as well as coping with symptomatic problems.

Indirect Open-Ended Suggestions

E: With enough experience he can go to Flagstaff and take with him his breathing habits of Phoenix. Because ***you can take habits with you.*** **That's one of the problems that the airline pilots have. They all grow up with clock habits. And their sleep cycle is disturbed. They have to learn how to get a changing sleep cycle. I'm talking to you while he** [H] i**s learning something.** ***He doesn't know what he is learning, but he is learning.*** **And it isn't right for me to tell him, You learn this or you learn that!** ***Let him learn whatever he wishes, in whatever order he wishes.***

This is another illustration of the senior author's indirect and open-ended approach to offering therapeutic suggestions that permit the patient's unconscious to find its own individual mode of optimal functioning.

Facilitating Unconscious Search and Unconscious Processes: Suggestion by

Surprise and Association

E: Now I mentioned the ringing in your ears. I mentioned blushing. I mentioned breathing. Elevating blood pressure, lowering it. You always have to be aware, and *we know a lot of things we don't know we know.* My friend Bill said he wanted to blush. He never had. I knew that he could get pale. He could get a red face in the heat. Blood would decrease in his face when he went to sleep. He had all those learnings. All I did was say something that took him by surprise. And he reacted that way. He did not know how to turn it off. But I so surprised him that the automatic working of his body wasn't in gear. All I said was OK, and his body went back into automatic gear.

W: Yes

In an indirect manner the senior author associates W's ringing-ear problem with the previous illustrations of successful coping with symptoms by learning to alter sensory-perceptual and physiological functioning. If he had directly told her at this point that she would have to learn to control the ringing in her ears, she would almost certainly have demurred and protested that she did not know how. She would be right. Certainly her conscious mind does not know how to alter the ringing. The control she will learn is still an unconscious potential at this point. By conversationally associating the ringing problem with the other anecdotes of successful perceptual alteration, however, the senior author is indirectly creating an associational network or belief system that will later enable W to accept further suggestions that will evoke and utilize whatever unconscious mechanisms she has available to effect a therapeutic transformation. Before she has any chance to discuss and possibly reject even this mild association, Erickson immediately shifts his remarks to the husband. Since she is intensely interested in learning trance by watching her husband, the wife's conscious attention is distracted to him, and the therapeutic association that Erickson just gave her remains lodged within her unconscious. This therapeutic association may now automatically begin a process of *unconscious search for the unconscious processes* that will eventuate in the therapeutic transformation to be experienced later as *a hypnotic response.*

Direct Suggestions in Trance

E: [To H] Now listen to me because you can listen to me. *You can have nice feelings in both feet, in both legs. You can enjoy having your heart beat strongly and gently. You can learn the feelings of breathing, the feelings of breathing that you have in Phoenix.* If your wife didn't learn swimming until she was fifty-five, I can tell her one thing she learned as soon as she got into the water. First time she went into the water up to her neck, she found it difficult to breathe.

W: I had to learn to relax.

E: And small children wading into the water find their breathing gets choked. And that scares them. After a while they learn to breathe with that water pressure against their chest. And when they learn to do that, then they don't use that learning outside the pool. As soon as they get back in the pool, they use that water pressure learning so they breathe

normally. ***Now he pays attention in the back of his mind to his Phoenix breathing patterns, habits, and when he goes to Flagstaff, he can keep on using those same muscle patterns, muscle habits.*** **Now in med school when you got into an air chamber with decreased air pressure and you notice how your breathing changes, you pay close attention to it. When you come out, you notice the change. You can go back in the air chamber and breathe comfortably because you start using your new breathing patterns.**

Erickson has carefully structured a therapeutic frame of reference about our ability to alter body functions before and during the initial stages of trance. H's response has been so positive that Erickson now judges that it is appropriate to drop a few direct suggestions into that therapeutic frame. Even now, however, he elaborates the direct suggestions with a further illustration about learning to alter body functioning while swimming. His choice of this particular example is very apt because it is very meaningful to both H and W; both have recently spoken of it. By choosing such illustrations close to the patients' personal life experiences, the therapist can make a sounder bond of contact with patients' inner lives and real potentialities.

Trance Induction and Facilitating Unconscious Processes

E: [To W] Now suppose you lean back and uncross your legs. Look at that spot there. Don't talk. Don't move. There is nothing really important to do, except go into a trance. You have seen your husband do it. And it is a nice feeling. Your blood pressure is already changing. You may close your ***eyes now*** **[pause as W closes her eyes and visibly relaxes her facial muscles] and go deeper and deeper into the trance. You do not have to try hard to do anything. You just let it happen. And you think back;** ***there are a goodly number of times this afternoon when you stopped hearing the ringing. It is hard to remember things that don't occur. But the ringing did stop. But because there was nothing there, you don't remember it.***

Having prepared her for trance induction by using her husband as a model, the senior author now induces trance with a few instructions that have three objectives: to fixate attention (look at that spot), to depotentiate her habitual frames of references (Don't talk. Don't move. There is nothing really important to do), and to give free reign to her unconscious (go into a trance).

He then states a common though little recognized fact about the experience of symptoms. Symptoms may seem constant and unchanging. Yet invariably there are moments when we are so distracted that they are outside the central focus of our awareness. This automatic mental mechanism that shifts our attention and thereby attenuates and usually completely obliterates the experience of the symptom is evoked as the senior author describes it. This little-recognized fact is usually received with a sense of surprise by patients - a surprise that further depotentiates their old symptom-laden frame of reference and initiates a *search on an unconscious level for those unconscious processes* that may now be utilized for symptom relief.

Relying upon Unconscious Learning: The Conditions for Direct Suggestion

E: Now the important thing is to forget about the ringing and to remember the times when there was no ringing. And that is a process you learn. **I learned in one night's time not to**

hear the pneumatic hammers in the boiler factory - and to hear a conversation I couldn't hear the previous day. The men had been told I had come in the previous evening, and I talked to them and they kept trying to tell me, But you can't hear us, you haven't gotten used to it. And they couldn't understand. They knew I have only been there a short time - one night - and they knew how long it had taken them to learn to hear conversations. They put their emphasis upon learning gradually. I knew what the body can do automatically. [Pause] ***Now rely upon your body. Trust it. Believe in it. And know that it will serve you well.***

The senior author now strongly emphasizes that symptom changes will take place via an unconscious process. It is important for the conscious mind to rely upon your body, trust it, and so on. He drops the direct suggestion to forget about the ringing" into the frame of reference he structured before trance induction in his story about learning not to hear the pneumatic hammers in his sleep at the boiler factory. Thus when direct suggestions are used, they are always placed like a key in the lock of a frame of reference that was previously structured by the therapist and accepted by the patient.

We can summarize the requisite conditions for the successful use of direct suggestion as follows:

1. - creating frames of reference as an internal environment or belief system that can accept the direct suggestion.

2. - patient's reliance on unconscious processes to automatically mediate the suggestion and new learning that is needed.

3. - therapist's partially evoking and thereby facilitating the utilization of such unconscious processes by illustrating them in ways that are personally meaningful in the patient's actual life experience.

Further Suggestions and Illustrations: Symptom Substitution; Synesthesia

E: Another patient of mine with ringing of the ears, a woman of thirty, said that she had worked at a war plant where there was music all day long,

and *she wished she could have that music instead of the ringing.* I asked her how well she remembered that music. And she named a great number of tunes. So I told her, use that ringing to play those tunes softly and gently. Five years later she said, I still have that soft gentle music in my ears.

She worked at a war plant in Michigan. You described a little boy and piano playing and the cassette, and you demonstrated with your hands the

way he moved his fingers. Part of the pleasure of seeing him, hearing him, became a part of your finger movements.

[Pause]

And you can put that part of pleasure with your finger movements into your ears. **And you can do it so easily, so gently, without trying, without even noticing.** ***And you can really enjoy good feelings, good sounds, and good quiet.***

[Pause]

And you both can breathe for us, and neither of you need to be concerned about the other. You need to enjoy knowing each other. ***And enjoying what you can do as meaningful to you.***

By now the reader can easily recognize how the senior author is offering further suggestions and illustrations of the sort of sensory-perceptual transformations that may effect symptom relief. As we will see later, by the end of this session, W was actually able to utilize one of these illustrations successfully for symptom relief. Notice again how carefully the senior author intersperses his suggestions with the woman's own relevant life experiences in pretending to teach the retarded child to play the piano. In suggesting, You can put that part of pleasure with your finger movements into your ears, he is actually trying to evoke and utilize unconscious processes of synesthesia whereby pleasure from one sense modality (kinesthetic or proprioceptive sensations from the fingers) could be shifted to another (her auditory perceptions).

Awakening from Trance: Facilitating Unconscious Processes by Learning and Utilizing Hypnotic Pain Control Without Awareness

E: You go into a trance, I suggest, by counting to 20, and awaken by counting backward from twenty to one, but each person should go into a trance in the way he learns naturally by himself, and you have learned an excellent way and it's your way and be pleased with it and be pleased with extending usefulness of that trance in many different ways. You both can learn from each other without trying to learn. There are so many things we learn from others, and we don't know we are learning. And our main, very difficult learnings ***we achieve without knowing that we are achieving those learnings.*** **And you both are very responsive people. Which in less technical language means** ***you both can learn easily things about yourself and learn them without needing to know that you have learned them. That you can use those learnings without needing to know that you know those learnings. I*** **am going to ask both of you to awaken gently and comfortably.**

In this awakening procedure the senior author incorporates many direct suggestions to emphasize learning without awareness. Ideally, learning to alter and transform the sensory-perceptual aspects of physical symptoms is an unconscious process that proceeds on an unconscious level. Consciousness usually does not know how to cope with these transformations and is best eliminated from the process. Erickson's last suggestion, That you can use those learnings without, needing to know that you know those learnings, contains some subtle implications. The patients can learn to use pain-transforming mechanisms on an unconscious level to such an automatic degree that they need not even know they are successfully dealing with pain. Since consciousness is not even aware of the automatic operation of these newly learned pain-control processes, consciousness need not know about the presence of current and future pain. The senior author has emphasized that pain has three components: (1) memories of past pain, (2) current pain, and (3)

anticipation of future pain. His last suggestion can be understood as a means of coping with the latter two without giving consciousness an opportunity to dwell on the process and possibly interfere with it. This approach is to be used with appropriate clinical caution. With this couple the pain did not serve any useful function as a signal about body malfunction that their physician needed to know. Thus their pain could be eliminated completely for optimal relief. When pain is an important signal about a body process that the physician needs to know about, then the presence of pain should certainly not be eliminated from consciousness entirely. In such cases the pain can be transformed into a warmth, coolness, itch, numbness, and other symptoms. The aversive quality of pain is thereby eliminated, but its signal value is maintained.

Facilitating Amnesia by Structuring an Associative Gap and Distraction

[Pause as they both reorient to their bodies by blinking, stretching, yawning, and so on.]

E: My daughter spent three years in Africa. She is married to an Air Force officer. And he was assigned to Ethiopia. Shortly after her arrival in Ethiopia, she remarked to her husband, You see that statue? That is just exactly what my Daddy likes. Yes, she knew I would like it. It was a statue of a woman, and how can you describe it?

[Shows statue to the group]

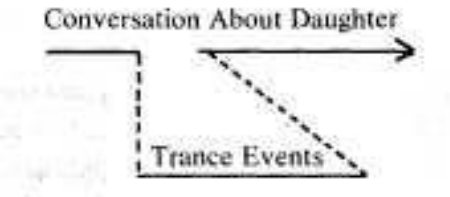
R: It's very unique.

E: It is a weird looking thing.

W: She knew you would like it?

E: She knew I would like it! I was delighted when I saw it. And my son picked out that little rug right there on the floor. He mailed it to me for a birthday present ten years ago. He knew I would like it. When I unrolled it, my two young daughters in grade school commented, That is not North American Indian? Is it South American Indian? My wife said, It isn't Indian! I said, It is Hindu. . . .

The senior author demonstrates two means of facilitating hypnotic amnesia in these few remarks made immediately upon the awakening from trance. He first returns to a topic of conversation about his daughter that came just before trance induction. By picking up an associative thread from this period, the trance events are placed into an associative gap. Trance events and associations cohere together, but there are no associative bridges to the patient's mental framework (a conversation about Erickson's daughter in this case) which occur immediately before or after trance. Because of the relative lack of associative bridges, trance events tend to remain dissociated from the patient's habitual frameworks and may thus become amnesic. The following diagram may clarify the matter (Erickson, Haley, and Weakland, 1959), where the upper line is a conscious memory line with only a small gap that tends to cover the lower line of trance events.



The senior author's second approach to facilitating amnesia is to distract the patient from trance associations by introducing topics of conversation that are far distant from the trance work that has just been completed (in this case gifts, rugs, Indians.) These distracting topics also tend to prevent the development of associative bridges between the contents of trance and the contents of the awake state, thereby facilitating an amnesia for trance events. This amnesia is often therapeutically valuable, since it prevents the patient's limited and maladaptive belief systems from later working and possibly undoing the suggestions accepted during trance. The amnesia also tends to vividly ratify trance as an altered state for the patient.

Spontaneous Acknowledgment of Therapeutic Change

H: Well, doctor, I'll say this. This has done as much good as that other one has done. This is going to be wonderful.

E: You'll be surprised at all the new learnings that both of you will develop.

W: Good, Good.

E: We will call it a day.

[The session is ended, but just before she leaves the woman comments as follows]

W: When I think of the ringing in my ears now, I'm beginning to think of a melody that I play. One of several that I like very much. Now the ringing is still there but the melody is there also.

This acknowledgment of an immediate experience of therapeutic change came spontaneously from both patients. This is the ideal situation, where the therapist does not have to ask about the change and by doing so possibly distort the change process itself. Some patients might take such a question as implying a doubt in the therapist's mind, while others would tend either to exaggerate or to underestimate the amount of change experienced.

The husband expresses an important and valuable expectation of present and future therapeutic gains (this is going to be wonderful), while the wife, more analytically, describes how a melody is being added to her ringing. It is hoped that future work may entirely replace the ringing with the melody. Since both spontaneously acknowledge a satisfactory therapeutic change, there was no need for the senior author to end this session with any further evaluation and ratification of therapeutic change. (This final stage of evaluation and ratification will be well illustrated in our next case.)

Case 2 Shock and Surprise for Altering Sensory-Perceptual Functioning: Intractable Back Pain

This is another case where Erickson worked simultaneously with husband and wife. This couple was in their early twenties, however, and they came to therapy in a very negativistic and doubting mood. Because of their extreme doubts Erickson used a very dramatic approach to establish rapport, response attentiveness, and trance induction.

Archie and Annie were high school sweethearts. They were idealists who went ahead with their plans to be married even after Archie's back was broken and his spine severed in the Viet Nam war. Archie had returned to civilian life permanently in a wheelchair with intractable back pain. His physicians said he would have to learn to live with it. They had warned him against any sort of black magic with hypnosis, which was certainly not worth his time. Archie and Annie nevertheless wanted to try, although by the time they came to their first interview they were in a hostile, negative, and doubting mood regarding their prospects.

The senior author's first task was to recognize and accept their hostility and doubt and, if possible, actually to utilize it in some manner. He had to accept their negative frame of reference and yet introduce his own belief in the potential value of hypnotherapy. Erickson watched a few of Archie's spasms of pain and recognized that they were of psychogenic origin, much like that of phantom limb pain. After listening to the outline of their story, he decided to demonstrate a dramatic form of trance induction with Annie in order to orient Archie to the genuine therapeutic potential of hypnosis.

Trance Induction: Displacing and Discharging Hostility and Doubt

Erickson first asked Annie to stand in the middle of a small Indian rug about a yard in diameter that was on his office floor. He then proceeded with an unusual trance induction.

E: Annie, you are not to move off that carpet. And you are not going to like what I am doing. It will be offensive to you. It will be offensive to Archie. Now here is a strong oak cane, Archie. You can hold it and you can clobber me at any moment that you think I am doing wrong. You won't like what I'm going to do, Archie, but watch me carefully and clobber me just as soon as you think it is necessary.

Now I'm going to take this other cane and you watch what I'm doing. You will feel what I'm doing Annie. Archie will see what I'm doing. I will stop as soon as you close your eyes and go into a deep trance.

The senior author gently and tentatively touched about her upper chest area with the tip of his cane and then began to gingerly push the upper part of her dress apart, as if to expose her breasts. She closed her eyes, remained rigidly immobile, and apparently went into a deep trance. She had to escape the unpleasant reality of that cane. As soon as she closed her eyes and manifested a trance state, Archie was so surprised he almost dropped his cane.

What are the dynamics of such an induction? With his apparently shameless poking about Annie's dress, Erickson was channeling their very evident hostility and vague doubts about hypnosis in general into a very specific rejection of Erickson's initial behavior. Annie was so constituted psychologically that she had no alternative in the situation.

The poking cane certainly fixated her attention, and the shock of it all certainly depotentiated whatever conventional mental framework she had about how doctors behave and what hypnosis was about. As she stood there, desperately uncertain about what was happening, she was sent on an unconscious search for the trance-inducing processes within her own mind that would release her from her embarrassment. The senior author said he would stop only when she went into trance. She could only escape the unpleasant poking by going into trance. She need not reject the whole situation outright, because, after all, her husband was right there with a stout cane supposedly protecting her. By giving Archie the cane, the senior author was very carefully giving him a channel through which he could focus his hostility. He was also fixing Archie's attention so intently that the young man was in that state of intense response attentiveness characteristic of therapeutic trance as he watched the unorthodox proceedings with disbelief. Thus his general doubt and disbelief about hypnosis could now be channeled, displaced, and discharged onto the apparently ridiculous behavior he was witnessing. Without quite realizing it, he also became convinced that Erickson could perform the unspeakable, the unorthodox, and, by implication, an unusual cure.

A Two-Level Posthypnotic Suggestion to Utilize and Depotentiate a Doubting Conscious Framework

E: Annie, when you awaken, you can sit in your chair, and *no matter what you think, whatever I say is true.* Do you agree to that?

[Annie nods her head yes repetitiously in the slight and slow manner characteristic of the perseverative behavior of trance.]

Whatever I say is true, no matter what you think.

This was a carefully formulated two-level suggestion: (1) No matter what you think is a phrase recognizing her conscious doubts that enables Erickson to focus her attention by utilizing her own mental framework of doubt and resistance. She could think whatever she liked within this doubtful frame. At the same time (2) on an unconscious level she was to make true or real whatever Erickson was to later suggest. We could also say that two realities or belief systems were permitted to coexist side by side in a more or less dissociated manner: (1) The conscious belief system of doubt and resistance to hypnosis that she brought to the therapy situation, and (2) the new reality of hypnosis Erickson was introducing in such a suddenly shocking manner that neither she nor her husband could properly evaluate and understand it. She was permitted to indulge in her previous belief system even while Erickson's reality was being introduced in a manner that she could not avoid or resist. Whatever the doubts or resistances of her previous beliefs, she was certainly not prepared to cope with a cane probing her dress while her husband stood poised with another heavy cane ready to clobber the crippled doctor. Since her conscious

mental framework could not cope with the situation, her unconscious had to intervene with the appropriate responses of going into trance and accepting Erickson's suggestions.

The senior author assessed and deepened her trance by obtaining her positive response to his two-level posthypnotic suggestion. He then asked her to awaken and sit down. She sat down with a look of expectation, doubt, and hostility. He then addressed her as follows.

Truisms, Implication, and Not Knowing to Initiate an Unconscious Search

E: Now you are awake, Annie. You don't know what has happened. ***You can think that you wish you knew, but you don't know.***

With this the senior author was stating the obvious. Certainly Annie did have questions on her mind about what, if anything, had happened. Thus the truth of the first part of the statement, You can think that you wish you knew opened a yes or acceptance set for the critical suggestion that follows, but you don't know. This suggestion is critical because it implies that something important did happen, but she does not know what. The implication that *something happened* means she may no longer be what she has always experienced herself as being. The something that happened may be hypnosis; it may mean she now will be able to experience whatever reality Erickson is going to suggest. The *not knowing* thus opens a gap in her belief system that initiates an unconscious search for the internal resources (unconscious processes) that will be needed to carry out Erickson's further suggestions. Not knowing thus facilitates the utilization of inner resources that she had never been able to contact previously in a voluntary manner.

Surprise Question for Not Doing

E: Aren't you surprised you can't stand up?

With this suggestion in the form of a question, Annie did indeed experience amazement at not being able to stand up. The senior author said she would be surprised, and she certainly was. His question quickly filled the gap and expectation that had been opened in her belief system by setting into operation mental processes that somehow prevented her from standing up. Annie probably did not know why she did not stand up. Neither was she aware that the senior author had also prescribed her reaction of "surprise at not being able to stand up. Certainly it was true that she would be surprised at not being able to stand up. His question was thus another obvious truism that anyone would have to accept. Even without the previous gap having been opened in her belief system, this question of surprise could stand as beguilingly effective suggestion that anyone would have to accept as true. And most would also experience its implication of the involuntary behavior of not being able to stand.

Self-Test for Anesthesia

E: ***No matter how hard I struck you with this cane, you would not feel it. And suppose you take your hand and hit yourself hard on the thigh. It's difficult for me to come over and do it myself, so go ahead. Hit yourself as hard as you can on your thigh. It won't hurt!***

With this Annie did indeed strike a numb thigh and was startled at the effect. She replied, I felt it in my hand but I didn't feel anything in my leg. Having successfully experienced one fairly easy hypnotic phenomenon in not being able to stand, Erickson judged that she was now ready to experience the really important phenomenon of anesthesia. He made a veiled threat with the thought of striking her with his fearsome cane, so that she cannot help but feel some relief at being permitted to test the anesthesia by herself. Erickson then offers further relief with the fact that he really cannot come over to her (since he is crippled) and thus reinforces her further for a successful self-test of anesthesia. Erickson (Erickson, Rossi, and Rossi, 1976) has stated, The unconscious always protects the conscious. Certainly Annie did feel a need for protection at this moment. The protection came from her unconscious, which effectively mediated the neuropsychological mechanisms that permitted her to say she had indeed experienced an anesthesia in her leg. Pressing on, the senior author now extends the anesthesia further.

Generalizing Anesthesia

E: ***Now Annie, you can hit your thigh again but won't feel it in either your thigh or your hand.***

The senior author now generalizes her successful anesthesia of the thigh to her hand by associating them together in this strong direct suggestion. Annie then slapped her thigh again and exclaimed, I heard that slap, but I didn't feel it in my hand or my thigh. Thus Annie spontaneously confirmed the reality of the anesthesia to her husband. He could doubt Erickson's explanations, but he could not doubt his wife's reactions. Hence the negative attitude induced by his physician was not disputed by his witnessing Annie's experience - it was depotentiated. That is, he was now experiencing a suspension of his previously doubtful and disbelieving frame of reference. Before he could reassert his doubt, Erickson quickly introduced him to a formally labeled trance.

Compound Suggestion Introducing Trance

E: ***You heard that, Archie, you can go into trance now.***

Annie's experience was an effective use of modeling hypnotic behavior for her more resistant husband. The senior author then formally induced trance with a compound statement. You heard that was an undeniable truth that opened an acceptance set for the suggestion, Archie, you can go into trance now. Archie could not deny the reality of his senses regarding his wife's experience, and thus had to accept Erickson's suggested reality of trance.

Utilizing Previous Sense Memories to Replace Pain: A Pun

E: Now, Archie, you've had many long years of happy feelings. Why not get those *happy feelings back?* You've had all the pain you need.

With such suggestions the senior author began to evoke Archie's sense memories of previous years of good body feelings before his back injury. These memories of good body feelings will be *utilized* to replace his current pain. Notice the therapeutic pun contained in the phrase happy

feelings *back.* Without realizing it Archie was receiving associations of happy feelings with his injured *back.*

Realistic Expectations of Pain Relief and Booster Shots

E: I cannot guarantee you against all future pain, but I can tell you to use pain as a warning.

With such suggestions Archie was able to experience considerable relief from pain. A few months later he caught the flu and telephoned Erickson for a booster shot, since with the flu there was a recurrence of back pain.

R: Why was there a recurrence of back pain with the flu? Were his body and mind debilitated so he could no longer maintain the hypnotic suggestion of good feelings? Is it the same situation as with you, Dr. Erickson, that when you go to sleep you sometimes lose your own hypnotic control over your body pain? [E's pain is due to constantly atrophiating muscles associated with his second bout with anterior poliomyelitis.] Is hypnosis being mediated on the highest cortical levels which are sensitive to body illness as well as sleep?

E: Yes, just as I induce a trance on the highest cortical level.

R: People really are not asleep in trance; in fact, there is a high degree of mental activity. Perhaps those who say everyone cannot experience trance means you cannot put everyone in a sleeplike state of being an automaton responding indiscriminately to everything that is suggested.

E: Yes, you cannot put everyone into such a passive or submissive state.

R: By hypnosis and trance you mean focused concentration, focused attention. You certainly can facilitate that with anyone whose motivations and needs you understand.

E: Therapeutic trance is focused attention directed in the best manner possible to achieve the patient's goals.

Case 3 Shifting Frames of Reference for Anesthesia and Analgesia

E: When I want a patient to develop an analgesia, I'm very likely not to mention this question of analgesia. I'm very willing to let the patient tell me all about that pain until I can see from the expression on his face that he thinks I understand. I'm not averse to saying a few things, little things that makes the patient think I do understand. And then I'm very likely to ask him some simple question that takes him far away from this question of the pain: Where did you spend last summer? The patient can be rather surprised at that question about last summer. Last summer he didn't have that pain. We can go into the question of the pleasures and joys and satisfaction of last

summer. Emphasize comfort, physical ease, joys, and satisfactions, and point out to the patient how nice it is to continue to remember the joys and satisfactions of last summer, the physical ease of last summer. When the patient seems to be getting just a little bit edgy, I remind him of when he was rowing the boat and got that blister on his hand. It hurt quite a bit but fortunately healed up.

I haven't been afraid to mention hurt or pain or distress, but it is far away from that backache the patient started telling me about. I've mentioned pain from a blister due to rowing a boat last summer and I haven't been shocked by that uneasy expression on his face. *Because you see in hypnosis your task is to guide the thinking and the association of ideas that the patient has along therapeutic channels.* You know very well that you can have a painful spot on your body and go to a suspenseful movie and lose yourself in the action on the screen and forget all about that pain in your leg or the pain in your arm, aching tooth or wherever. You know that, so why not do exactly the same sort of thing with your patient? If you are operating on a patient in your office and you are aware of the fact that it can cause pain, you can direct your patient's thinking to an area far removed from the pain situation.

I'm thinking of a patient of mine who said, I'm afraid to go to the dentist, I agonize so much, I perspire so frightfully, I'm in absolute misery. I asked the patient immediately, Did you do that as a child?

I was listening to her complaint about pain, anxiety, distress, and I asked her what she did in her childhood. I made good contact with her by talking of the distress she was interested in, but I shifted to another frame of reference - childhood. She now talked about her childhood distress, but that was so far away that it was less disturbing and she felt a bit more comfortable. My next step was to ask her what her favorite pleasure was as a child. Now, how do you get from pain, anxiety, distress, to pleasure as a child? In this case it took only two associative steps. It was so delightful to switch and discuss with me a favorite activity of her childhood. Now she discussed this pleasure in immediate connection with my first question of her experience of distress in childhood. By that immediate succession of questions I tied the two together - distress and favorite activity.

After she told me all about her favorite pleasures as a child, one in particular, I suggested that when she went to the dentist's office, she should really settle in the dental chair. As she really squirmed around in the chair and really felt her seat on the chair seat, her back on the back of the chair, her arms on the arms of the chair, and her head on the headrest, she would have an overwhelming recollection of her favorite childhood activity that would absolutely dominate the entire situation. Now, what had I done? I had taken the painful realities of the dental chair, squirming around trying to get a nice comfortable seat (and I wiggled around in my seat to role-play the way I wanted her to find herself in that dental chair), and associated it with one of her favorite childhood activities. The thing that she remembered was playing in the leaves on the lawn. In the autumn you can build great big houses out of the leaves, nice pathways through piles of leaves, you could bury yourself in the leaves. You could squirm around and get nice and comfortable in those leaves and the rest of the real world would seem far away.

With that she simply went into a very nice anesthetic trance in the dentist's office without any

direct suggestions for anesthesia. Now and then the dentist would ask her some stupid question when she really wanted to think about the leaves. The dentist thought that she was an awfully cooperative patient. Mentally she would notice that here was some stupid person trying to talk to her when she was burying herself in the leaves, probably some grownup yelling at her, but she was more interested in the leaves. She could have dental surgery done and not be bothered by it.

You can achieve anesthesia indirectly by shifting the person's frames of reference. In this case the critical shift was to, What was your favorite activity as a child? And then I could really elaborate on that. *In other words, you very carefully raise a question. You raise it in such a way that you can slide past the difficulty and start up another train of mental activity, of emotional activity, that precludes the possibility of feeling pain.* Some of my sophisticated subjects with training in clinical psychology and psychiatry, that I have used as subjects, will pick apart the technique that I have used on them. They then recognize the validity of it from their own experiences. They will have me employ precisely the same techniques on them again because they know that they are human and that you can do the same thing with pleasure, over and over again.

I think it is an error to always strive to get an anesthesia or an analgesia directly. I think you should be willing to accomplish them indirectly because every time you ask somebody Forget that this is a watch, you're asking them to do a specific thing - to forget - to forget what? A watch. Now, remember, forget that watch. That's what you're saying when you say," Forget the watch. But you can ask them to look at this, an interesting thing. It rather amuses me. It's rather fascinating how you can look at something and become tremendously fascinated with it, and then the topic of conversation changes, and you drift far away to that trip you had in Europe. Now what was it I came up here for? You drifted far, far away from your original preoccupation because you started following your different trains of thought.

Now the next thing that you should bear in mind is that when you take away the sense of feeling, anesthesia or analgesia, you've asked your patient to make a different kind of a reality orientation. In some of my earliest experimental work I asked students to discover what the mental processes were in picking up an imaginary apple and putting it on a concrete reality table in front of them (Erickson, 1964). What are the mental processes? A goodly number of the students complained of feeling funny all over and gave up the task; they left without completing the experimental situation. They were losing their contact with reality. Therefore, they felt funny. Now when you induce an analgesia, you are asking your patients to lose a certain amount of their reality contact. You are asking them to alter it. Then they begin to feel funny - they may recognize it or they may not. But they can react to that by getting out of the situation because it is strange and uncomfortable. Therefore, whenever you induce an analgesia or an anesthesia, you must see to it that your patients don't get frightened in one way or the other by the loss of their usual reality relationship. I let those students feel funny all over and let them run out on me because it was an important experimental finding that I wanted to study.

In working with patients in the office, when they get a funny feeling, whether they recognize it as a funny feeling or they just experience it as discomfort, they want to run out, too. But they can't afford it, and neither can you. Therefore, it is your obligation to tell them that one of the astonishing things is that as they begin to feel more comfortable or they get more and more interested in this or that, perhaps they will notice the light in the office is of a softer hue. Quite

often I have told patients in my office, I hope you don't mind here as we continue our work if the light automatically dims and becomes softer or lighter." Whenever their reality orientations are altered, I know patients are going to tell me the office is getting lighter or darker, or getting warmer or colder, or they feel afraid, or that they feel the office is getting bigger or smaller, that they are feeling taller or shorter. They get all manner of changes in their sense of reality whenever we explore anesthesia or analgesia. These spontaneous sensory-perceptual alterations are all indications that the patients' reality orientations are altered; trance is developing whether a formal hypnotic induction has been carried out or not. As patients learn to be more comfortable with these spontaneous alterations, they can allow themselves to go deeper into trance. They learn to give up more and more of their generalized reality orientation (Shor, 1959), and they become more capable of experiencing all the classical hypnotic phenomena as well as achieving their own therapeutic goals.

Case 4 Utilizing the Patient's Own Personality and Abilities for Pain Relief

E: I wanted to produce an anesthesia, a relief of terminal cancer pain for Cathy. She was suffering intolerable pain that could not be relieved by morphine, Demerol, or anything else. She was in a desperately debilitated state of mind in which she just repeated, Don't hurt me, don't scare me, don't hurt me, don't scare me, don't hurt me, don't hurt me. A continuous, monotonous, urgent crying out of those two particular sentences. My opportunity of intruding upon her was rather small. What could I do in order to bring about a relief of the pain? I had to use Cathy's own learnings. I had to use my own thinking, and my thinking, of course, would not be in accord with the thinking of this high school graduate who knew she had only a couple of months left to live. She was thirty-six years old with three children; the oldest was eleven years old. Therefore, her thinking would be totally different, her desires would be so totally different, all of her understandings would be totally different from mine, and my task was, of course, to bring about a hypnotic state in which I could stimulate her to do something with her own past learnings. I didn't want to try to struggle in a futile way when the woman had already learned morphine had no effect on her, when Demerol, no matter how large the dose, seemed to have no effect on her. I didn't want to try to struggle with her and tell her she should go into a trance, because that would be a rather futile thing. Therefore, I asked her to do something that she could understand in her own reality orientations. I asked her to stay wide awake from the neck up. That was something she could understand. I told her to let her body go to sleep. In her past understandings as a child, as a youth, as a young woman she had had the experience of a leg going to sleep, of an arm going to sleep. She had had the feeling of her body being asleep in that hypnagogic state of arousing in the morning when you are half awake, half asleep. I was very very certain the woman had some understanding of her body being asleep. Thus the woman could use her own past learnings. Just what that meant to her, I don't know. *All I wanted to do was to start a train of thinking and understanding that would allow the woman to call upon the past experiential learnings of her body.*

I did not ask her to contend with me about going into a trance, because that, I thought, was futile. I did not ask her to try her level best to cooperate with me in going into a trance, because she

didn't know what a trance was. But she did know what being wide awake was. She did know what a body being asleep was, because she had a lifelong experience of both states. The next thing I asked her to do after her body was asleep was to develop an itch on the soles of her feet. How many people have had itches on various parts of their bodies? Miserable itches, uncontrollable itches, distressing itches. We all have had that sort of experience, therefore I was again suggesting something to her that was well within her experience, within her physiological, psychological, neurological experience; within her total body of learnings. I was asking her to do something for which she had memories, understandings, and past experience. I was very, very urgent about this development of an itch. The woman shortly reported to me that she was awfully sorry she could not develop an itch. All that she could do was to develop a numb feeling on the dorsum of the foot. In other words the woman was unable in her state of pain to add to her state of pain. She did the exact opposite. She developed a feeling of numbness, not on the sole of the foot, but on the dorsum of the foot.

Now, what was my purpose in seeing her? That is the thing that all of you should keep in mind in dealing with patients. *You are seeking to alter their body experiences; their body awareness; their body understandings; their body responses.* Every change that develops should be grist for your mill, because it means that the patient is responding. When Cathy told me she had the numbness on the dorsum of the foot, I accepted that as a most desirable thing and I expressed regret, politely, that she had not been able to develop an itch. Why did I express a polite, courteous regret that she had not developed an itch? Why should I criticize or find fault with my patient's responses? I should be gracious about it, because Cathy had a lifelong history of experience with people who had been courteous, who had expressed regret, and who thereby put her at ease since earliest childhood in various situations. Cathy had a background of experience into which my courteous regret could fit.

Now the point I am trying to establish is this: When you talk to patients, talk to them to convey ideas and understandings in such a way that your remarks fit into the total situation with which you are dealing. You try to elicit an ever-widening response on the patients' part so that they respond more and more with their experiential learnings, with their past memories and understanding. Cathy could accept my apology and feel obligated. Since she failed me in one regard, she could feel obligated to put forth more and more effort on the thing that I accepted. While accepting Cathy's numbness on the dorsum of her foot, / *also utilized her own background and personality to intensify her efforts to please me.* Since I had been so gracious in accepting her failure to produce the itch, I intensified her motivation to cooperate with me in any further tasks.

The next thing I did was to suggest that the numbness extend not only over the dorsum of the foot but perhaps to the sole of the foot and the ankle. Well, of course, in suggesting the sole of the foot where Cathy had failed to put an itch, she would be all the more eager to produce the numbness. As surely as she did that, she would be obligated to develop a numbness of the ankle. Of course Cathy had had plenty of experience being unaware of the sole of her foot, unaware of her ankle. Cathy knew what numbness was, and she had body learnings of those things. Therefore, when I asked her to do those things, she could make a response. Now Cathy was not paying any attention to her bed, to the pictures on the wall, to the presence of the other physician with me, to the tape recorder that was in full view. Cathy was directing her mental attention to her body learnings. In the use of hypnosis you need to be aware of the total unimportance of external

reality. Now as Cathy developed the numbness in the sole of her foot and the numbness in her ankle, she withdrew more and more completely from the reality of the room. She was giving her reality orientation to her body, not in terms of cancer pain but in terms of body learnings of numbness. Cathy became very greatly interested in letting the numbness progress from her ankles to the calf, to the knee, to the lower third of the thigh, the middle third, the upper third, having it cross over to the other side of her pelvis and go down the other leg so that she had a numbness from the umbilicus down. Now that interested Cathy. At that moment, of what interest was the ceiling, the bed, the doctor, the walls, or anything else? Cathy's interest was directed to that state of numbness just as dental patients should be so fascinated by the thought of the control of capillary circulation, by the thought of dental anesthesia, by the thought of learning how to chew their food with a different kind of bite so that they won't have temporal mandibular pain. The thing that interests the patients, the reason they are in your office, should be the point of orientation.

With Cathy oriented to the numbness of her leg and pelvis it was a simple matter to extend the numbness up to her neck. Cathy had metastases throughout her torso, she had lungmetastases, metastases in the bones in the spine as well as the bones of the pelvis. When you consider that sort of thing, you make every effort to extend the numbness. Here is a patient who knows that she is going to die within a few months. She has been assured of that by physicians whom she trusts and believes, so death is an absolute reality, while the walls of the room, the bed itself might not be an important part of reality. This matter of impending death, this matter of her family, was an unforgettable reality, and so in dealing with her experience of pain it was necessary to include some of the ordinary reality of her daily existence. Cathy had had that cancer for about a year. If I want to help Cathy, I have to organize any hypnotic suggestions that I give her in such a fashion that they incorporate some of Cathy's own thinking, some of Cathy's own understanding. The first thing I did for Cathy in the matter of numbness of the chest was to mention that her cancer first started in her right breast and then to mention that there was still an area of ulceration at the site of the surgery and that that ulcerated area was painful. That is a bit of external reality but it is also a bit of body reality, because Cathy could look down at that ulcerated area, which made it external to her because it was something she was looking at. The pain was a personal experience within her body. The visual thing was external and unpleasant and disagreeable, and that external vision could threaten her life. The pain and distress was an internal experience so far as Cathy was concerned. Therefore, I made Cathy aware of some of the external environment. She was already aware of the internal environment, so I merely made certain to include external environment, but an important part of external environment. The walls in her bedroom, the pillows on her bed, weren't important parts of external reality, but her visual impression of that ulcerated area was a most important part of her external orientation, and so I directed her attention to that.

Cathy had expressed regret because she had not been able to develop an itch on the sole of her foot. What should I do? Now, too many operators, too many people who use hypnosis try to be perfectionists, they try to accomplish too much. That is one of the reasons for failure in many instances - the effect to try to accomplish too much. Any student in high school or college will tell you: certainly I can't make 100, I might make 95, or I might make 90, I can't do better than an 85, I am lucky to get an 80. We have that sort of an orientation. Even the expert marksman says: I hope to get 10 out of 10, but I am not at all certain of that. Expert bowlers would like to make a certain score, but they never really honestly expect in every game to have a perfect score; they

expect a certain amount of failure. Those who use hypnosis had better bear in mind that the patients they are working on have a lifetime of experience in expecting a certain amount of failure. You, as the therapist, ought to utilize, you ought to go along with, the patients, and you ought to be the one that picks out the area of failure. It was tremendously important that Cathy be relieved of that pain, but she had an experience of going to high school Cathy knew by virtue of a lifetime of experience that she could not achieve perfection in her performances. Therefore, in suggesting relief I was very very careful to ensure a certain percentage of failure. What had failed Cathy in the first place? Her first failure was in that right breast, that is where the cancer started, that is where she had her first sense of personal failure. Her right breast had let her down. Her right breast had doomed her. There is no way of getting around that understanding on Cathy's part. That right breast had doomed her. So now I express my sorrow, my regret that I couldn't take away the pain at the site of that awful ulcerated area on her chest. I recognized aloud to Cathy that that was a minor pain, a minor distress, and I was awfully sorry that I failed. Now Cathy could agree with me, and she could agree with me when I wished that I could produce the same numbness there that I had produced elsewhere in her body. In other words I made use of the double bind: As long as she had distress at the breast area, she had to have numbness elsewhere in her body. Thus I had all of Cathy's general experience substantiating the numbness of most of her body.

Now, there is nothing magical about what I did - *it was a recognition of the thinking that Cathy would do . . .* the thinking and the understanding that would derive out of Cathy's ordinary life. A woman who grew up in this culture, in this age, would have certain learnings as a result of just being alive. Now, when I left that minor pain, that minor distress, it proved that I was not God. It just gave Cathy another goal to strive for, even though she had the feeling that she would fail as far as this minor pain was concerned. Cathy lived from February, when I saw her, until August. She lapsed into coma and died rather suddenly. But during that length of time, Cathy was free of pain except in this one particular area, but as Cathy said, she didn't hold my failure against me. Why should she? By letting her keep that minor pain, I ensured the success of the rest.

We need to understand the way we behave emotionally. We can take only so much, but there is always one last straw. In the use of hypnosis we make use of that particular learning: We get rid of everything but leave that last straw as a distraction because it is a minor thing. I removed the major part of her pain but just left that last straw which Cathy could consider unimportant. Now I have stressed this because I want to impress upon you the tremendous importance in *offering your suggestions not as the thing the patient is to do but as the stimulus to elicit patient behavior in accord with individual body learnings, individual psychological experiences.* I suggested an itch on the foot, which would be adding to her pain. My purpose was not really to produce an itch on the sale of her foot. My purpose in suggesting that was merely to start Cathy functioning within herself - to start Cathy using her own body learnings and to use them according to her own pattern of response. Then when Cathy developed the numbness on the dorsum of the foot and expressed her regret, I used that regret and numbness. I could use it intelligently to bring about the relief of pain that would meet Cathy's needs. When I first approached Cathy, I had no understanding at all about how I could produce a relief of pain for her, because I didn't know her. I knew nothing really about the uniqueness of her own individual learning. My initial task was to say something that would get Cathy's attention and allow her to make her own personal responses. I then utilized those responses. In the use of hypnosis in medicine, dentistry, and

psychology there is a need to explore the kind of thinking and responding that is characteristic of the individual patient. We need to recognize the actual unimportance of what we say as being the goal to be achieved. *The importance of what we say lies in its being a stimulus for the elicitation of responses peculiar to the patient. We then help the patients utilize these responses in new ways to achieve their therapeutic goals.*

Selected Shorter Cases: Exercises for Analysis

In this section are summaries of cases by the senior author and others illustrating the basic principles we have explained. Some are reported here for the first time; others have been published elsewhere. The student would do well to analyze the dynamics of their effectiveness in terms of the concepts introduced in this and precedings chapters. Some guides for this analysis are placed in italics at the end of each case.

A Tiger Under the Bed

A woman dying of terminal cancer was brought to Erickson's office in an ambulance. She was in desperate pain, and drugs no longer diminished it. She was frankly skeptical of hypnosis and immediately told Erickson of her doubts upon entering his office. He proceeded impressively as follows: Madam, I think I can convince you. And you know how much pain you are suffering, how uncontrollable it is. If you saw a hungry tiger walking through that doorway, licking its chops and looking at you, how much pain would you feel? She was apparently stunned by this unexpected question and said, Not a bit. In fact, I'm not feeling any pain now either. Erickson then replied, Is it agreeable to you to keep that hungry tiger around? She said, It certainly is ! All the associations to hungry tiger had so focused her attention that she was in a walking trance, from which she need not be awakened. She presented the entire appearance of being awake in all other respects. Yet she could see and experience the presence of that tiger at any time, day or night. The hypnotherapist simply evokes surprising sets of emotional, cognitive, or behavioral responses to interfere with the symptoms he needs to alter.

The senior author then told her that her doctors and nurses might not believe it, but she now experienced the truth of pain relief. And, indeed, her physicians and nurses did not understand. Whenever they came to offer her an injection for pain relief, the woman responded with a warm smile, No, thank you, I don't need any. I have a hungry tiger under my bed. They suspected she was hallucinating and perhaps losing contact with reality, but in those last months of her life she lived in apparent comfort without the use of narcotics or tranquillizing medication. Her family thought she was just fine, however.

Shock; Surprise; Fixation of attention; Common everyday trance; Distracting associations; Altered frames of reference; Posthypnotic suggestion to protect the therapeutic work

Chin on a Chair

The senior author has had to deal with personal pain problems all his life because of poliomyelitis. He usually can control pain effectively during the daytime by simply going into autohypnotic

trance. When he gets very tired or goes to sleep at night, however, the pain sometimes returns and wakes him up. He then has to rearrange his muscles and mental composure to get rid of the pain again. Sometimes in the middle of the night this is just not easy. On such occasions he confesses to having sometimes pulled a chair to the side of his bed, hooking his chin over the back of the chair, and pressing down until he could no longer stand the pain he produced voluntarily (Erickson and Rossi, 1977).

Hypnotic suggestion as a highly developed cognitive frame of reference that can sometimes fail during sleep; Distracting involuntary pain with voluntary control over pain

Shaggy Dog Stories

Then there was the patient with paralysis from the level of the twelfth thoracic vertebra who had severe recurring attacks of pain associated with an acute cystitis and poliomyelitis. He would endure his pain until he could no longer control his outcries. Since his general condition was chronic, narcotics were inadvisable. Because he was an earnest, sincere, considerate, socially-minded man, but totally lacking any sense of humor or capacity to understand wordplays and puns, his pain was handled by the simple procedure of instructing the nurses to tell him shaggy-dog stories, especially those employing word-plays and puns. He would listen earnestly, appreciative of the sociability of the nurse, and struggle absorbedly in trying to make sense of her narrative. As time went on the patient spontaneously would summon a nurse and state that his pain was starting up - could she spare a minute or two of her time to talk to him, and he would try to understand her story.

Fixation of attention; Distraction; Unconscious search and processes

Head and Shoulder to the Solarium

In a case of terminal-illness pain in a woman with a young daughter the senior author addressed the young daughter as follows: Now your mother wants to be convinced that she can be free from pain. That is what you are going to do - convince your mother. Now just sit in this chair here, and while you're sitting in that chair, go into a trance and go over to the other side of the room. And I want you to lose all sense of feeling everywhere. You will be without feeling in a deep trance. You are sitting here, but you're over there on the other side of the room and you are watching yourself there. . . . Now you watch, mother. Your daughter is in a deep trance. She thinks she's on the other side of the room. Now keep your eye on me because I'm going to do something that no mother would ever want done. I rolled the girl's skirt up to expose her bare thighs. The mother looked on in horror as I did that. I raised my hand and I brought it down on her thigh with a terrific slap. The girl was watching herself on the other side of the room. Now I can't slap a girl on the other side of the room, can I? The mother was aghast that there was not a single wince out of the girl. Then I slapped the other thigh. The girl was still comfortable.

This mother was highly addicted to television so I eventually taught her that whenever she had a pain she could not tolerate, she was to leave her body there in bed and take her head and shoulders out into the living room and watch T.V.

This dissociative approach to pain relief was one of the senior author's favorites. In hospital practice he would frequently have patients take their head and shoulders out to the solarium while their surgeon did the necessary work on their bodies in the operating room.

Shock; Surprise; Modeling hypnotic behavior; Dissociation

Numb with Conversation

The conversational approach to fixating and holding the patient's attention can be very useful in traumatic stituations. There was an automobile accident in Portland, Oregon, and a man skidded on his face on a gravel road for about thirty feet. A gravel dirt road. He was brought into the hospital as an emergency case. One of the members of the American Society of Clinical Hypnosis - we will call him Dan - who does a great deal of plastic surgery and oral surgery was on emergency call that night. He went in and found that the man was conscious and suffering a great deal of pain. Those of you who know Dan know what a marvelous talker he is. He has a steady stream of words, of humor, of interest, of information, a tremendous wealth of knowledge and humor. Dan said, You really filled your face full of gravel and you know what kind of a job that makes for me. I've got to take tweezers and pick out every confounded little granule of sand and dirt and I am really going to have a job and I've really got to mop up that face and get half the hide off it and you have been suffering pain and you want some help out of it and you really ought to get some kind of pain relief and *the sooner you start feeling less pain the better* and I don't know what you ought to do while you're waiting for the nurse to bring something to inject in your arm but you really ought to listen to me while I am talking to you and explaining to you that I have to do certain things about your face. You know there is a gash here, that must have been a pretty sharp stone that cut that one, but here is a short one and here is a bad bruise and I really ought to mop it off with alcohol. *It will hurt at first a little, but after it is done a few times the sting will deaden the tip of the nerves that are exposed and you stop feeling the sting of the alcohol,* and did you ever try to make a violin? You know you can make violins out of myrtle wood, you can make them out of spruce wood. Did you ever try making one out of oak? Dan had won a national award for the best tone violin that he himself built out of myrtle wood, and Dan kept up his steady stream. Now and then he discussed the tremendous difficulty of really mopping up that face and putting in the stitches and wondering when the nurse would get around to the hypodermic. All the while, behind him, the nurse was passing Dan the right sort of instrument, the right sort of suture, the right sort of swab, and so on. Dan just kept up that steady stream and the patient said, You are awfully gabby, aren't you? Dan said, 'You haven't heard me at my best I can talk with a still greater rate of speed just give me a chance and I'll really get into high. Then Dan started getting into high, You know I think fast too and did you ever hear anybody sing the Bumble Bee? I'd better hum it to you. So Dan hummed the Bumble Bee and finally he said, You know that is about all. The patient said, What do you mean about all? Dan said, Here's a mirror, take a look. The patient looked and he said, When did you put in those sutures? When did you clean my face? When did I get an injection? I thought you were just talking to me, just getting ready. Dan said, I've been working hard for over a couple of hours, about two and a half hours. The patient said, You didn't. You've been talking about five or ten minutes. Dan said, No, take a look, count those stitches if you want to, and how does your face feel? The patient said, My face is numb.

Conversational approach; Fixation of attention; Distraction; Inter-spersal of suggestions; Time distortion

Calloused Nerves

Recently I had a patient sent to me with chronic hip pain. Very serious pain. I knew better than to try to induce a direct trance in the patient. What did I need to do? Everything I said to that patient, I think, was horribly unscientific, but the patient wanted certain understandings that she could accept, that could justify that chronic uncontrollable hip pain. I accepted the patient's absolute statements of uncontrollable pain. I accepted every one of her statements, so she knew that I believed and thought the way she did. Then I began an entirely specious explanation of how that pain came about, so that the patient could understand it in terms of her own frames of reference. 1 explained how that hypodermic shot of penicillin or whatever it was, probably had a needle with a ragged point and in being stuck in the hip, hit the sciatic nerve. I explained how the tip of the needle could tear nerve fibers, and I gave a long dissertation on the structure of a nerve. It is not just one single fiber; it is made up of many many fibers. I gave a dissertation on the different kinds of sensations that travel over the fibers. You get heat traveling on one fiber and cold on another, and a touch on another, and pressure on another, until that patient thought that I was rather erudite. Finally, when she was rather bored with this increasing hodgepodge of information, I threw in a suggestion here and there about pain wearing out, of the body becoming accommodated. A laborer with tender hands such as mine would have blisters very promptly using the pick and shovel. But with the pick and shovel wielded a half minute one day, a minute the next day, a minute and a half the third day, and a gradual progression in the length of time, there would be a callous formation until the pick and shovel could be handled all day long. I threw in all sorts of apparently sensible analogies. I pointed out that callous formations can be the skin of your hand and that one can also become used to emotional deprivation. In other words one can form emotional callouses, one can form intellectual callouses, dermal callouses, nerve callouses - all that sort of thing, until the patient listening to me began accepting all of those suggestions and began on her own to seek a way to use them to help herself lose pain. Every one of those things that I said about callous formation had the effect of the patient's thinking: Yes, I know what callous is. I wish I could have a callous at the nerve in my hip where all that pain is. How nice it would be. How would my leg feel if I had a callous there? It would feel this comfortable, as comfortable as my other leg does. I presented ideas that the patient could find acceptable, but I wasn't asking her to accept those ideas. I was merely explaining possibilities, explaining them in such a way that the patient had to reach out and pull in whatever ideas she needed to facilitate her comfort. Now what is this suggestion? I think that this woman with hip pain was in the kind of trance that was effective for her. I did not dare attempt to induce a formal trance that she could recognize, because I knew she would then think the calloused nerves was just my idea that I was trying to force on her.

Yes set; Specious suggestion fitting the patient's frame of reference; Boredom depotentiating conscious sets; Interspersed suggestions initiating unconscious searches and processes; Indirect associative focusing: Indirect ideodynamic focusing; Open-ended suggestions

CHAPTER 6

Symptom Resolution

The basic view of modern psychosomatic medicine is that symptoms are forms of communication. As such, symptoms are frequently important signs or cues of developmental problems that are in the process of becoming conscious. What patients cannot yet clearly express in the form of a cognitive or emotional insight will find somatic expression as a body symptom. The conventional psychoanalytic approach to such problems is to facilitate insight so that the language of body symptoms is translated into patterns of cognition and emotional understanding. It is sometimes found that when patients can talk about their problems with emotional insight, they no longer need to experience their body symptoms.

Hypnosis has been an important tool in the evolution of this basic view of psychosomatic medicine (Zilboorg and Henry, 1941;Tinterow, 1970), and continues today as an important modality for the resolution of symptomatic behavior. The senior author's major contribution in this area is the discovery that while emotional insight is usually a very desirable approach in resolving psychosomatic problems, it is by no means the only route. He has developed ways of resolving symptomatic behavior directly on an unconscious level." That is, symptoms may be resolved by working with a patient's psychodynamics in such a manner that consciousness does not know why the body symptom disappears. Moreover, the developmental problem that was expressed in the symptom is also resolved in an apparently spontaneous manner. Patients are usually pleasantly surprised by this. They say they did not even realize the therapist was working on their sexual problems, their educational problems, or whatever.

Two-level communication is our basic approach to working directly with the unconscious. We use words with many connotations and implications, so that while the patients' conscious frames of reference are receiving communication on one level, their unconscious is processing other patterns of meaning contained in the words. The senior author likes to point out that he uses folk language" or intimate language" to reach deep sources within the patient. He uses such mythopoetic processes (Rossi, 1972b) as analogy, metaphor, puns, riddles, jokes, and all sorts of verbal and imagistic play to communicate in ways that bypass or supplement the patient's usual frames of reference (Erickson, Rossi, and Rossi, 1976).

Why are such processes effective? We believe they work because they utilize the patient's own life experiences and previous patterns of learning in a therapeutic manner. A pun or a joke can bypass an erroneous and limiting conscious framework and effectively mobilize unconscious processes in ways that the patient's conscious intentionality could not.

Recent research in hemispheric functioning (Gazzaniga, 1967; Sperry, 1968; Galin, 1974; Rossi, 1977) suggests that the effectiveness of these approaches may be in their appeal to the right, or nondominant, hemispheric functioning. While the left, or dominant, hemisphere is proficient in processing verbal communications of an intellectual or abstract nature, the right hemisphere is

more adept in processing data of a visuospatial, kinesthetic, imagistic, or mythopoetic nature. Since the right hemisphere is also more closely associated with emotional processes and the body image (Luria, 1973; Galin, 1974), the view has developed that it is also responsible for the formation of psychosomatic symptoms. These symptoms are expressions in the language of the right hemisphere. Our use of mythopoetic language may thus be a means of communicating directly with the right hemisphere in its own language. This is in contrast to the conventional psychoanalytic approach of first translating the right hemisphere's body language into the abstract patterns of cognition of the left hemisphere, which must then somehow operate back upon the right hemisphere to change the symptom. That approach sometimes works, but it is obviously cumbersome and time-consuming. All too often the patient develops marvelous patterns of intellectual insight, yet the body symptom remains. Even if the intellectual insight to the left hemisphere is correct, it may remain isolated from the right hemisphere's sources of symptom formation and maintenance. Thus, while the senior author developed the two-level communication approach long before our current understanding of left and right hemispheric patterns of specializations, we now believe that this working directly with the unconscious may be a means of communicating directly with the right, or nondominant, hemisphere, which is probably responsible for psychosomatic symptoms.

Case 5 A General Approach to Symptomatic Behavior

Miss X, who had plans to become a professional harpist, consulted the senior author for help with her problem of sweating palms and fingers. Her hands were usually damp, and when she tried to play in front of an audience, the perspiration was so great that her fingers would slip off the strings. The numerous medical doctors she consulted were both amazed and amused that she could hold one hand extended and soon form a puddle on the floor of the perspiration dripping steadily from her hand. They recommended a sympathectomy but could not be sure even that would solve the problem.

A salient feature of this initial session was the senior author's indirect exploration of the possible relation between the symptom of sweating and sexuality. His clinical experience has been that this symptom is usually associated with a problem in sexual adjustment. Since Miss X presented sweating as her only problem, however, his clinical judgment was to explore the possible relation between the excessive sweating and her sexuality indirectly by two-level communication. He did this by utilizing puns, certain words, and turns of phrase with double meaning, intonations, and pauses that may evoke sexual associations within Miss X if they are in fact associated with her problem. Rather than directly confront her with a clear statement about sexual problems in a manner that might arouse resistances, he simply provides contexts, implications, and association patterns that will enable her to bring up the sexual problem by herself. If he happens to be wrong in his clinical hypothesis about the sexual etiology of her symptom, nothing is lost; Miss X simply will not pick up and utilize the sexual associations.

There is a certain difficulty in presenting this material in a convincing manner in written form, because so many of the possible sexual associations are cued by intonation of voice, pauses, a certain smile or glance, etc. To facilitate the reader's understanding, words and phrases that could arouse latent sexual associations - if they are, in fact, present in the listener - will be italicized.

In the first part of the interview the senior author is involved in the process of preparation. A positive rapport and response attentiveness are established, and he begins to assess which of her abilities may be utilized. He facilitates therapeutic frames of reference and heightens her expectancy of receiving help. He initiates a process of two-level communication whereby he explores the possible sexual etiology of her problem and utilizes her special interest in music to enhance her first experience of therapeutic trance. We witness many of his approaches to depotentiating limitations in her conscious frames of reference and an interesting approach to symptom dynamics during what appears on the surface to be a simple process of hand levitation.

In the second part of this interview he leads her into a deeper experience of trance, during which she is very evidently engrossed in inner work. By the third and final part of this interview he is using ideomotor signaling to evaluate and ratify the process of therapeutic change that has already taken place. During this interview we witness with unusual clarity the logic of his general approach to symptomatic behavior:

1. 1. He establishes rapport and focuses attention into a therapeutic frame of reference.

2. 2. He demonstrates with the patients' own experience how their unconscious controls their behavior. This is a means of depotentiating their habitual framework and belief systems so he can then assign the locus of therapeutic change to the patients' unconscious.

3. 3. He utilizes the indirect forms of suggestion (in this case particularly two-level communication) to evoke searches and processes on an unconscious level that may initiate a change in the dynamics of symptom formation.

4. 4. He then demonstrates the resulting therapeutic change via ideomotor signals and/or the patient's obvious release from symptomatic behavior.

5. 5. He then allows the patient to fully recognize and appreciate the significance of the psychodynamic insights about the source and meaning of the symptom that frequently come up spontaneously at this time. Ideas and attitudes facilitating a general enhancement of the patient's total life experience without the symptom are explored and integrated.

As will be seen, the first three steps may appear in varying order. They may appear almost simultaneously or in sequence, with varying degrees of repetition depending on the needs and responses of the individual patient. The successful demonstration of therapeutic change in Step 4, together with posthypnotic suggestions for the maintenance of this change, usually sets the stage for the broader patterns of new understanding and life reorganization that frequently take place in Step 5.

Together these five steps constitute a paradigm of our general approach to symptom resolution. Within this paradigm the therapist may explore one or more psychodynamic hypotheses about the source and maintenance of the symptom. The senior author's exploration within the two sessions of this case was so indirect, however, that we were not able to ascertain whether his hypothesis about the sexual etiology of Miss X's problem was correct. It wasn't until he received a letter three months after the termination of therapy, wherein Miss X confirmed that sweating was no

longer a problem and that she had simultaneously resolved an important sexual difficulty, that we had confirmation that his two-level approach was correct and therapeutic.

This case thus arouses fascinating questions about the possibilities of a hypnotherapy based on the utilization of a patient's own creative potentials rather than the older tradition of hypnosis as a form of direct suggestion. We observe that it is possible to release a patient's creative potentials in such a way that a problem can actually be resolved without patient or therapist really knowing the exact why or dynamics of cure. In the second session, however, the senior author does support the symptom-removal work of the first session by facilitating the growth of Miss X's insight regarding the etiology of her excessive sweating and related problems of claustrophobia, fears of flying, and her general life orientation. It will be seen in this second session that the idea of simple symptom removal is a gross oversimplification of what sound hypnotherapy can be. The hypnotherapist is more appropriately involved in the broader program of facilitating a creative reorganization of the patient's inner psychodynamics so that life experience is enhanced and symptom formation is no longer necessary.

SESSION ONE

Part One: Preparation and Initial Trance Work

Trance Induction with an Indirect Exploration of Sexual Associations by Two-Level Communication

E: Now the first step, of course, is to *untangle your legs.* And untangle your hands. Now *what do you think I should do?*

X: Well, to be perfectly honest with you, I guess I probably feel that .you *ought to hypnotize me. In that if you don't, I might be aware of what you are doing,* and that would wreck it.

E: All right, now what is your education?

X: I have a master's degree in social work.

E: *Untangle your legs,* of course, has sexual associations. Untangle your hands means no more resistance.

R: These simple changes of body position tend to lower resistance immediately.

E: *What should I do?* Ever make love to a girl? Recognize the sexual connotation in that? It is pleasing to a girl to let her make the decisions. But these implications need not be consciously recognized. She feels I *ought* to, but she is not telling me I have to. To hypnotize her would be the proper thing. *If you don't, I might be aware of what you are doing,* may be a two-level communication implying a recognition of sexual connotations right from her unconscious.

R: It can be a two-level communication even if she doesn't recognize it on a conscious level. This then is your first use of two-level communication to explore the possible sexual etiology of her problem.

Facilitating a Therapeutic Frame of Reference: Separating Conscious from Unconscious

E: Then you know something about the conscious mind and the unconscious.

X: Yes.

R: Here you begin the process of introducing a very important therapeutic frame of reference, distinguishing between the conscious and unconscious mind. Once patients come to realize and accept the reality of an autonomous and potentially creative unconscious system that is different from their conscious system (which is bogged down with a problem), they are immediately within a more therapeutic frame of reference, because they now have a rationale for giving up some of their older ways of doing things and are more open to new experience within themselves. Even for those readers who think of the unconscious as a mere metaphor, however, it is useful to make this separation between conscious and unconscious because of the therapeutic double binds you can later set up with this division.

The Pause as an Indirect Form of Hypnotic Suggestion

E: *And when you dream at night,* what part of your mind are you using?

(these breaks in the transcription approximate the natural pauses in the senior author's speech.)

X: The unconscious?

E: Yes, and that does not prevent you from knowing the next day *what you dreamed about, does it?*

X: That's right, sometimes.

E: Yes. The conscious mind is usually pretty busy with itself, but it can be aware of the unconscious mind.

E: *When you dream at night,* your imagination is unfettered.

R: Therefore, the pause after the word night allows that first phase of the sentence to be momentarily associated with sexual connotations. The pause that isolates a phrase with its own implications and connotations is thus another indirect form of hypnotic suggestion.

E: The tone of my voice in saying *What you dreamed about, does it?* also carries sexual connotations.

Indirect Sexual Associations Interspersed in Trance

Preparation

E: *All right, so that eliminates this question of preventing you from knowing what I'm doing.* You can know what I'm doing, but I can also do some things you don't know about. All right, what is *your favorite piece of music?*

X: My favorite piece of music? I think, uh, Y's Harp Concerto in F Minor.

E: Do you know what tone deafness is?

X: Yes.

E: I am tone deaf.

X: I know. I noticed you are wearing purple.

E: The first sentence in a suggestive tone of voice reinforces the earlier sexual connotations. *Music* has sexual associations, as when you turn on soft music to make love. Favorite piece also has sexual connotations for some.

R: So this is actually an association on two levels: To the conscious mind it is an inquiry about her interest in music; to the unconscious, however, there are the sexual associations to music.

E: All this material is on two levels.

R: On the conscious level you are talking about preparation for trance and her interests. There are many implications and connotations to the particular phrases you use that can arouse sexual associations on an unconscious level, however.

Rationale of the Indirect Approach to Sexual Associations

E: I am also partly color blind. *I can enjoy purple.* And how well can you enjoy that piece of music?

X: Immensely.

E: You are sure of that? Lean back in your chair. I can daydream about things *not really looking at anything. Not really listening to anything.* And I can listen to the *whispering* of the wind in the woods. *And you are in position to start* listening to some part of that *piece of music.*

E: *Purple*love is a colloquial term for wife-swapping. I'm putting together my enjoyment (purple) with her enjoyment (music) and making them comparable.

R: On the conscious level it is a conversation about things you enjoy. On the unconscious level, however, there are important sexual associations which *purple*and *music* have in common.

E: *That's a good position* has obvious sexual associations. When you kiss a girl, she is *not really looking at anything.* When you look at many of these words and phrases from a sexual point of view, you can see they are really loaded.

Trance Induction Utilizing Internal Music

E: ***Just listen slowly to it.*** ***And you really don't need your eyes open.*** **And really thoroughly enjoy that piece of music. And**

there was ***a time*** ***when you did not know that piece*** **of music. A**

time when you were learning it and ***a time when you began enjoying***

it fully **and more fully.**

R: Your trance induction is now well on its way with a comfortable body position, a fixation of her attention of her own inner music, and the casual suggestion that she does not need to keep her eyes open. Trance induction is thus a comfortable process that develops almost imperceptibly out of a conversation about her interest in music.

Soon to Introduce Suggestions

E: And soon you realize you are in a trance.

It is a very comfortable way to be.

E: Soon is the undefined future.

R: So you are always safe when you give a suggestion introduced with soon.

Hallucination Training

E: And not only do you want to be in a trance, but you want to hear that music continue ***over and over again*** **and then another piece of music comes to mind.**

E: There is no music in this room.

R: But this suggestion reinforces the hallucinatory aspects of her inner music. She could become so preoccupied with it that she may hear it as filling the room like a tone hallucination. This is actually the first step in training her to experience an auditory hallucination.

E: *Over and over again* has sexual connotations.

Suggestions Bypassing Resistance: The Conscious-Unconscious Double Bind

E: And you don't really have to pay attention to me. You give your attention to the music, but your unconscious mind will understand what I say and understand things that you can't understand. First of all, I want your unconscious mind to give to you to give to you *a most comfortable feeling all over.* [Pause]

R: This is your typical approach to bypassing conscious sets and resistance to suggestions. While her conscious attention is focused on her inner music, another part of her mind is registering what you are saying without comment or resistance.

E: Yes.

R: Is this also an example of the conscious-unconscious double bind? Because she does not know what her unconscious mind can do or is doing (because it is unconscious), she can only agree with you. She has no basis for denying what you say.

E: Yes.

R: Her 'unconscious understanding what her conscious cannot is another double bind that depotentiates consciousness by greatly limiting the sphere in which it can understand and make judgments.

E: Relieving consciousness of the need for action.

Double Tasks and Confusion for Bypassing Conscious Attention

E: And the next thing I want is for your unconscious mind to know that there is a very significant purpose for it to listen to me. And while your unconscious mind is listening to me, your conscious mind will be very busy listening to music of all kinds. Particularly phrases of music from here, from there, contrasting. But your unconscious mind is going to be listening to *anything* that I say to it. And it is very *meaningful* to your unconscious mind. [Pause] Now your unconscious mind knows that you can consciously lift your hands and move them.

R: You create a sharp division between the comfortable feeling her conscious mind can recognize and a strong request for attention from the unconscious. She is thus poised between comfort on one level and tension on another.

E: Yes. It is an urgent solicitation for her unconscious through her conscious mind.

R: Yet that urgent solicitation must reach her unconscious through her conscious mind?

E: Her conscious mind will not pay attention; it won't even bother to remember, because I've assigned the music to her conscious mind. You can use a double task to depotentiate

consciousness. *Confusion* as well as *assigning an absorbing task* are both ways of getting consciousness out of the way.

R: You structure this even further with a compound sentence that begins with the suggestion your unconscious mind is listening to me. The unconscious listening is then reinforced by the second half of the sentence, your conscious mind will be very busy with listening to music of all kinds - when she does, in fact, get engaged with her inner music. Recent research (Smith, Chu, and Edmonston, 1977) has established that it is possible to so occupy one cerebral hemisphere with music that the activity of the other is facilitated.

You seem to be so specific when you begin a sentence with the word particularly, but then you end with the most general music from here, from there, so no matter what she hears, it will be within your suggestion. Then even while the conscious mind may be busy contrasting different phrases of music, you suggest her unconscious will be listening to you. You established within your own scientific research and clinical experience that the mind can be so occupied with two tasks at once. It is well illustrated in your 1941 paper on The Nature and Character of Posthypnotic Behavior.

E: Yes.

Double Negative to Depotentiate Conscious Sets

E: But your unconscious mind knows that you don't know that it can lift your hands.

R: This is a truism in double-negative form, the not-conscious (the unconscious) knows that you *don't* know, which tends to confuse and further depotentiate her conscious sets.

Associating Symptoms with the Unconscious

E: Your unconscious mind knows that it can produce sweating, but I think your unconscious mind should know more than that. [Pause] And I want your unconscious mind to be willing to learn *anything, just anything* that I instruct your unconscious mind *to learn.* [Pause] *That is very nice* consciously to be busy with music and various memories from way back then to the future of your dreams.

R: In your first mention of her problem of sweating you immediately associate it with her unconscious. She, of course, knows it is related to her unconscious, since she cannot control it. What she does not realize is that you have been developing a relationship to her unconscious that she herself does not have. This implies that you will have therapeutic control over her symptom through your relation to her unconscious.

E: Yes. I mention the symptom and remove it [from the realm of her conscious mind's responsibility] to her unconscious mind and add *anything* to it.

R: You have assigned the symptom to her unconscious mind?

E: Very definitely, and I have assigned the symptom to *anything* which has sexual connotations when expressed with certain undertones.

R: This is rather remarkable: You have associated her symptom with its unconscious etiology without her realizing what you were doing.

E: And if that association was inappropriate, her mind would simply not register it. I said to learn with a slight sexual connotation in my voice and then that is very nice with the same connotation.

Limiting Conscious Understanding

E: And your unconscious mind is free to limit itself to things that I say. [Pause] I want to teach you something very much. Your hands are resting on your*thighs,* and your conscious mind is going to leave them *down there.*

R: In this compound statement your pauses are so spaced to first express a truism: Your unconscious mind is free. This initiates an acceptance or yes set that opens the mind to accept the important suggestion that follows, to limit itself to things that I say.

E: The phrase to things that I say also limited itself to conscious memories and conscious understandings.

R: Her unconscious is limited to the things you say, but why do you bring in the conscious?

E: I don't want her to know how freely I have been talking about sex.

R: By shutting off the conscious mind you obviate that possibility.

E: Yes, it can limit itself. The things I say are consciously heard but are understood on an unconscious level only. But the unconscious can keep those sexual connotations to itself. You don't allow the [conscious] self to become aware of it.

R: You then utilize the sexual connotations *of thighs.*

E: Yes. *Thigh*and *there; down there.*

Demonstrating Unconscious Control of Behavior

E: But vour unconscious mind is going to lift one or the other or both. I really don't know how your unconscious mind wants to learn.

R: Here you name many possibilities of hand lifting to assure your suggestion will be acted on in some manner or other.

E: Maybe it [the unconscious] is not going to lift up the hands because it wants to learn something

down there.

R: If there is a failure in hand levitation, can have psycho-dynamic significance; in this case sexual.

Threat and Enlisting Cooperation of the Unconscious

E: But I am going to find out as rapidly as your unconscious mind wishes me to learn. One or the other or both of your hands are going to lift up from your thigh very slowly.

E: But I'm going to find out is a threat. As rapidly as your unconscious wishes me to enlists the cooperation of her unconscious.

R: You first raise a tension and then state that the condition for the resolution of the tension is the cooperation of her unconscious. Is this a way of activating her unconscious?

E: Yes, when you offer a threat and then offer relief by cooperation, you have really enlisted the unconscious.

Separating Conscious and Unconscious: Not Knowing to Depotentiate Conscious Sets

E: Unconscious muscle movement is different from that of the conscious mind. And you are not going to know which hand is going to lift. You will have to wait and see, but you'll be uncertain. The mere tendency, first one hand and then the other, perhaps both, then one, then the other, perhaps both. Sooner or later an elbow is going to bend a bit, a wrist is going to lift up, a hand is coming up. [Pause]

E: I'm again separating the conscious from the unconscious by pointing out how body movements are different with each. Not knowing which hand is going to lift depotentiates conscious sets because it removes hand levitation from her intentionality. This ensures the involuntary lifting of the hand. It sets the conscious mind over in the other chair.

R: Where it can watch but not necessarily direct or control.

E: Yes.

Two-Level Communication

E: And it is going to be *very pleasant to wait.* And you've got a lot to learn about your hands. It is well worth the time, too. And your unconscious mind is already beginning to *explore.*That's right. It's *lifting.* A bit more. And sooner or later begins a minor *jerk.* [X's hands begin minor jerking movement up off her thigh. Much facial frowning is evident.]

E: *It is very pleasant to wait* also has sexual connotations. You just keep in mind all these ploys from everyday experience.

R: You use verbal ploys from everyday life to facilitate hypnotic suggestion. You simply intersperse words and phrases having certain connotations. On one level you are talking about the process of hand levitation, and on another you are evoking sexual associations. This would be an example of two-level communication (Erickson and Rossi, 1976)

E: Yes. *Lifting*all by itself as well *as jerk* also have sexual connotations on another level.

Confusion and Mental Flux to Maintain Open Frames of Reference

E: That's right [X's right hand begins momentarily to lift higher.] It doesn't necessarily mean it is that hand. It may be the other. It is still too soon for you to know. *Up it comes.* That's right. That's a beautiful unconscious movement. [X's hands are lifting with the slow, very slight, and apparently spontaneous bobbing and upward jerking movement that enables an experienced observer to distinguish it from the smooth lifting that is more characteristic of conscious voluntary movements.] That's another and another. You're really learning. That's right. And the wrist, and the elbow. That's beautiful. And now the right hand, indicating that it wants to join the left hand. I don't know if it will. That's right. Up toward your face. Elbows bending. And there is a bit of accommodation between the hands.

R: Your suggestions do not permit either hand to achieve a clear dominance in lifting. This tends to maintain her conscious mind in a state of confusion and creative flux. She is being maintained in a state of exploration and expectation rather than being prematurely fixated in the simple conviction that one hand is lifting. You are preventing her from forming a final and closed frame of reference around which hand is lifting. She does not realize it, but you are giving her an experience in maintaining a state of open, creative flux. This open state tends to facilitate the possibility of creative moments wherein she may break out of her old symptom-bound frame of reference to achieve a more adequate and therapeutic means of experiencing herself.

E: A common phrase in language is "not to let your right hand know what your left hand is doing.

R: So you are utilizing this form of dissociation to free her from conscious frames of reference that may be a source of her problem.

Utilizing Competition to Facilitate Hand Levitation

E: Which one will reach your face first? Left hand began first. Is moving faster.

E: Here I'm introducing competition between the hands. You work at a thing just so long, then you take a break. She has been working hard, so she can now take a break by doing something else.

R: She has been working hard at hand levitation, so now you give her a break by changing the task slightly to one of competition. The same goal of levitation is being achieved, but with a new attitude and source of motivation.

E: Yes, you are transforming one task into another. You alter the tension. [The senior author gives clinical examples illustrating how he utilizes patients' competitiveness to facilitate hypnotic experiences rather than have the patients' using their competitiveness to oppose the therapist. It is a basic principle of utilization theory to use a patient's personality characteristics to facilitate hypnotic experience.]

Two-Level Communication

E: But will the right hand suddenly increase its speed *and lift up?* That's it. [Pause] And you can take pride in that. Your unconscious is really taking over some control. And you are really beginning to learn that the unconscious can control. And it should be a pleasing thing to note how your hand moves, and you are a harpist, and *finger movements* are very important, and your unconscious is letting you know that. And even if the left hand gets halfway to your face first, that doesn't mean that the right hand can't catch up to it. [Pause] It may be the right elbow needs to be reminded that it can bend. Of course, the right hand can always have the *unconscious change its mind about the right hand movement.*

R: Here you are giving her unconscious a lot of apparent freedom by describing different possibilities of response; actually you are groping to find whatever response tendencies she has within her, and you then utilize them to facilitate the hypnotic experience of hand levitation.

E: And utilizing all the ploys of folk language: *and lift up* has a sexual connotation. Who will make the first move [in love play]? You want to make a girl blush? Talk about *finger movements.*

R: It has connotations of masturbation.

E: Right. Yet no one reading this would ever think of that. I have deliberately tested that out by asking patients, Tell me about your finger movements. The flush in their faces indicates the question has a sexual connotation.

R: So this is another clear example of communication on two levels: On the surface you are apparently utilizing her finger movements as a harpist to facilitate hand levitation; on another level you are activating possible sexual associations that will enable her to discuss or do something about her sexual problems.

Implied Directive for Deep Trance

E: Now your left hand is approaching your face, but the nice thing about it is that your unconscious mind won't let your left hand touch your face until you are really ready to go very deeply in trance and to do everything that needs to be done. Everything, even

though you don't know what everything is.

R: This is an implied directive that facilitates deep trance: Her unconscious won't let her hand touch her face until she is ready to go into a deep trance. You are relying on the patient's own unconscious to determine the moment for entering deep trance; you are utilizing the patient's own internal, autonomous mental mechanisms to facilitate deep trance. You have also made the suggestion to enter deep trance contingent on an inevitability: Her hand is going to touch her face from the way it is moving. The phrase and do everything that needs to be done is a very important all-inclusive suggestion that is hitchhiked onto the above in the form of a compound suggestion. Even though you don't know what everything is depotentiates consciousness further, so that the unconscious can work in its own way without the limiting preconceptions of her conscious sets.

The Negative to Displace and Discharge Resistance

E: And yet your left hand is moving up toward your face irresistibly, but it won't touch your face until your unconscious mind is really ready. And irresistibly it moves closer and closer. [Pause] And even though your left hand is very close to your face, that doesn't mean the right hand cannot beat it to your face. [Pause] A mere two inches to go, and I still don't know if your unconscious is going to lift your right hand to touch your face first. And that left hand less than two inches away. And now your unconscious mind is showing a *desire* that you don't know you have. That's right.

R: The use of the negative but it *won't* touch your face until your unconscious mind is really ready is very interesting. If she has any resistance your use of won't may pick up hers and redirect it in a constructive manner. Your use of the negative tends to displace and discharge the patient's resistance.

Inner Work as the Essence of Therapy

[Deep frowning and much grimacing by X.]

E: Your unconscious mind says there are some doubts, but you don't know what the doubts are. [Pause] And isn't it surprising to know how *desperately urgent* it seems to be.

R: What is the meaning of such frowning and grimacing? Is inner work being done?

E: Inner work is being done without her knowledge just as a school boy goes to bed at night without having been able to work out that arithmetic problem. He works it over and over in his mind. The next morning he notes the wrong digit and corrects the problem.

R: He did it in his sleep without being aware of it. So she is working on problems without being aware of them.

E: That is what she is doing: *All the therapy occurs within the patient, not between the therapist*

and patient. Desperately urgent" means she is going to be working on some important personal problem.

Implied Directive as an Ideomotor Signal

E: And now I know that your left hand is going to touch your face soon, and that will signify that you will be in a sufficiently deep trance. That you will hear and understand every word unconsciously that I want you to. [Pause] That's delightful to see those doubts. [Pause] As in the *irresistible force that is moving your hand,* and that's a relief. [Her left hand touches her face.]

R: This is another use of the implied directive that allows her own unconscious internal-guidance system to work its ways into the therapeutic process. You're using her hand touching her face as an ideomotor signal that she is in a sufficiently deep trance." Does your phrase you will hear and understand every word unconsciously that I want you to, allow her to interpret your words on an unconscious level in the way you want her to with their sexual connotations?

E: Yes.

R: Her frowning suggests she is experiencing doubts, so you utilize that doubt by defining it as delightful, which implies that it is somehow all right in the context of the inner psychological work she is undergoing. You then reinforce her for doing this inner work by mentioning that it is a relief' when her hand finally touches her face.

Preparation for Therapeutic Results: Two-Level Communication and the Cerebral Hemispheres

E: And now you can begin to feel a sense of competence and sureness that you haven't had for a long time. [Pause] And your hand feels so comfortable there. So comfortable you'll have to take a couple of minutes to realize how comfortable it is there. [Pause]

E: Telling her she can have a sense of competence and sureness prepares her for the therapeutic result.

R: Even before you deal with it?

E: I have dealt with it! She is frowning over it.

R: How have you dealt with achieving the therapeutic result?

E: By my two-level suggestions related to sexuality.

R: I see! By your use of two-level suggestion you have made her work on the sexual problem to the point where she was frowning even though she was not aware of it. That was the essence of your therapeutic approach, and now you are telling her that she will be well even though she may

not know why. This is really amazing! Under the guise of inducing trance by hand levitation, you were actually giving two-level suggestions to achieve a therapeutic goal. I notice you always seem to be doing two things at once. Your two-level communication may be selectively beaming suggestions to the left (conscious) and right (unconscious) hemispheres at the same time.

Reward and Posthypnotic Suggestion

E: And I am going to give you a special reward after you awaken from the trance, and you can wonder what that is. But you can go into a trance any time there is a good reason for it. You can go in by counting from one to twenty, or if I count from one to twenty, going one twentieth of the way each time. You can come out of the trance at the count of twenty to one, coming out one twentieth at a time. And you can all ways go into a deep trance. And you don't need to know any more than that you can all ways go into a trance when it's purposeful and meaningful.

R: Here you are facilitating a posthypnotic suggestion by arousing expectancy and motivation by mentioning a reward. Wonder is also a special word that tends to initiate an unconscious search and unconscious processes that may be useful. You then give your typical instructions for entering and awakening from trance by counting from one to twenty. You give an interlocking posthypnotic suggestion in a very casual manner that tends to depotentiate consciousness [you don't need to know.] Your suggestions are made highly acceptable to her since they are so protective and respectful, permitting her to go into trance when it is purposeful and meaningful.

E: All ways go into a deep trance is a two-level suggestion: On one level she hears you can always go into a trance ; on a secondary level it means you can go into a trance all ways , - that is, in many different ways. This is a posthypnotic suggestion that she will go into trance with whatever approach to induction you use. The secondary-level suggestion depends upon the literalism of the unconscious.

Indirect Suggestions for Amnesia, Hyperamnesia, and Posthypnotic Suggestion

E: And now, after you awaken, I want a bit of music that you haven't thought about or remembered for a long time to come suddenly in your mind when you see me plainly. And you can begin counting, mentally, silently backward from twenty to one beginning the count now. [Long pause as X reorients to her body and awakens.]

R: This is a posthypnotic suggestion that utilizes her own well-developed internal programs about music. Since you are requesting music that has not been thought of or remembered for some time, you are also attempting to lift an amnesia. In this simple way you are testing her capacity for hyperamnesia as well as posthypnotic suggestion. You tie the posthypnotic suggestion to an inevitable behavior, when you see me plainly, so she will have a clear cue to execute the posthypnotic behavior.

E: Yes, and I'm also tying in the first part of trance [where music is also mentioned].

R: With one sentence you are doing a number of things: You are probing for the possibility of a hyperamnesia in recalling a bit of music from childhood; at the same time you are structuring an amnesia for the actual content of her trance experience by tying the end to the beginning, so all in between tends to fall into a lacuna - an amnesic gap. When you administer posthypnotic suggestions, you typically use a buckshot approach, testing for many possibilities in order to assess what hypnotic talents a patient may have. But you usually administer these suggestions in an indirect, fail-safe manner.

E: And it is all so disguised that even the intelligent onlooker does not realize what I am doing.

Evaluating Therapeutic Trance for Indications of Change: Questions Evoking Posthypnotic Responses; Shifting Tenses to Facilitate Age Regression

E: Is it pretty? Can you tell us about it?

X: The music?

E: Yes. [Pause]

X: It changed.

E: Tell us what the change was.

X: From harp to an orchestra.
[Pause]

E: When was that?
[Pause]

X: When I was seven.

E: Where were you?

X: At home.

E: Who is in the room?

X: Who? [Long pause] My whole family, I think.

E: To your right or left?

X: To my right or left? To my left.

R: Your question uttered a moment after she focuses her gaze on you immediately reinforces the posthypnotic suggestion about music she has not heard for a long time.

E: The word pretty is childhood language to evoke childhood associations. When she asks, The music? it implies there were other things in her mind.

E: From harp, which is a solitary activity, to an orchestra, which includes *others.* So she is saying [on another level] that the change includes *others.*

R: The music changing to something she knew at the age of seven indicates the success of your posthypnotic suggestion. You then carefully question her about the circumstances surrounding the music to further extend the hypermnesia?

E: Yes. But also to talk about safe things. We are not going to risk talking about the *others.*There are two meanings to right and two meanings to left. They are loaded words. I'm using purposely double-barreled words.

R: Her conscious mind hears you questioning about the details of placement to the right or left. But on another level you are still on the track of Is something right or wrong?

E: Yes, and I'm directing it all to her. Notice how at a critical point I shift tense from the past (When *was* that? Where *were* you?) to the present (Who *is* in the room?). This shift in tense is an important approach to facilitating an actual age regression. Notice how her responses after that shift tend to imply she is reexperiencing the past.

Part Two: Therapeutic Trance as Intense Inner Work

In this first session the senior author has completed a basic unit of psychological work. He has established rapport and a good working relationship with the patient. He has made a preliminary survey of the problem and has introduced her to her first trance experience. Most surprisingly he has also made his first therapeutic approach via two-level communication without the patient's even realizing what he was doing.

This is an illustration of one of Erickson's basic approaches to hypnotherapy. He first sets up a therapeutic frame of reference by emphasizing and letting patients have an experience of the difference between the conscious and unconscious mind. With the process of hand levitation she is able to experience the difference between the voluntary lifting of the hand and the involuntary movements of the unconscious. While she is open to unconscious experience, he initiates a process of two-level communication: On one level he talks about hand levitation, while on another level he is using associations with sexual connotations. If her problem has a sexual etiology, these connotations will tend to activate her own sexual associations and lead her to the source of her problem.

At this point a number of alternatives are possible.

1. The Unconscious Resolution of a Problem.

The activated sexual associations may remain at an unconscious level, where during trance they

are turned over to effect an apparently autonomous resolution of the patient's problem. It is possible that hypnotherapy can take place entirely at an unconscious level without the patient (and sometimes even the therapist) knowing the why of the cure. The patient only knows a problem has been resolved. No insight in the conventional psychoanalytic sense is involved. This is probably the means by which the miracles of faith healing take place. Somehow or other something in the faith frame of reference touches off the relevant unconscious associations to effect an autonomous inner resolution of a problem. Of the many who apply themselves for such faith cures, however, relatively few experience these happy accidents. They are, indeed, so rare that they are called miracles.

With the two-level communication approach, however, the senior author is increasing the odds of a happy accident by making an educated guess about the sexual etiology of the problem. If he is right, then merely activating sexual associations during the relatively free and creative period of trance will increase the likelihood of a therapeutic interaction that can lead to an apparently spontaneous resolution of a problem on an unconscious level. The fact that the patient is in a therapeutic environment where cures are somehow effected by a not-too-well-understood process of trance tends to depotentiate her limited and erroneous conscious frame of reference and enables her unconscious to resolve the problem. This assumes that a therapeutic potential already present in the patient was blocked by the patient's erroneous frames of reference. Therapeutic trance is a relatively free period wherein patients can sometimes bypass these limitations so their own therapeutic potentials can operate without interference.

On its most basic level hypnotherapy can be effective simply by providing patients with a period of therapeutic trance so their own unconscious resources can resolve the problem. If the therapist has some understanding of the etiology and dynamics of the problem, then he may help focus the patient's unconscious resources by two-level communication. If the therapist is wrong in his assumptions, two-level communication is a subtle process that simply will not be picked up or acted upon by the patient's unconscious. It is thus something of a fail-safe procedure. The therapist is not likely to antagonize or bore the patient with erroneous and irrelevant ideas that may sound fine in a textbook but have little application to that patient.

2. The Activation and Expression of Relevant Associations to the Problem: Insight Therapy

A period of therapeutic trance with or without the help of two-level communication may stimulate associations to a problem that the patient wants to talk about. This route naturally leads to insight therapy. After an initial experience of trance the therapist may simply wait for the patient to bring up relevant associations. If none are forthcoming, the therapist may again review the nature and possible sources of the problem to ascertain if the patient now has more access to relevant associations. This was the course that the senior author began to explore by asking the harpist the details of her inner experience with music. Not much was forthcoming, and he felt the material was still too threatening for her to discuss it with the observers present; therefore, he again structures the conscious-unconscious therapeutic frame of reference and another experience of trance.

SESSION ONE

Part Two: Therapeutic Trance as Intense Inner Work

Structuring the Therapeutic Conscious-Unconscious Frame of Reference

E: By the way, are you right-handed?

X: Am I right-handed? Yes.

E: Are you right- or left-thumbed?

X: Right.

E: Put both hands above your head like this. Up higher and interlace your fingers. Lower hands. Lower them down. Is your right thumb on top?

X: No, it's my left thumb.

E: Now you have known that since you were a tiny tot.

X: That I was left-thumbed?

E: Yes. See, now that was your unconscious knowledge.

R: Here you do your right- or left-thumbed routine to again assert the importance of her unconscious.

E: Yes, I'm illustrating that there are things in her unconscious that she has known for a long time and did not know it. Further, I can prove it with her own behavior!

Spontaneous Ideomotor Responses Revealing Unconscious Knowledge

E: Are you a right of left kisser?

X: [X looks puzzled and then almost imperceptibly tips her head to the right with a slight quiver.] Left?

E: Oh, no! Did any of you see her?

R: I'm not sure I know what you are looking for.

E: Now again. Are you a right or left kisser?

X: [She now with more awareness tips her head slightly to the right.] Right!

E: What did you do the first time?

R: She tilted to the right very slightly and did not even know it.

E: So that proves she is a right kisser. It is startling how much we are learning about you. What time do you think it is? Don't look at your watch.

X: Twenty minutes of one.

E: Now look at your watch.

X: Not bad.

R: Only ten minutes off.

E: To explain that: A musician has a tremendous sense of time.

R: Yes. So she would not show so much time distortion.

E: How long did it take you to wake up?

X: Two minutes?

R: You use this approach with kissing to demonstrate the superior knowledge of the unconscious, but you are bringing it closer to the sexual area.

E: Yes, but harmlessly.

R: As you ask these questions, you watch her head and lip movements very carefully to detect the minor, unconsciously determined motor movements that will betray the answer. As I tried to answer that question about being a left or right kisser for myself, I noticed that I spontaneously made a slight tilt with my head. That tilt was an ideomotor movement that provided a kinesthetic cue I needed to answer the question. You ask questions that can only be answered by the kinesthetic knowledge of the body and point out how such knowledge belonged in the unconscious before you brought it to conscious attention. This initiates a process of ideomotor signaling that is frequently unrecognized by the patient.

E: Now this is an awfully threatening situation.

R: That's why you immediately shift to the time question. You've made your point about the potency of unconscious knowledge, and you now reinforce it with the question about possible time distortion during her previous trance. When time distortion is present, it tends to ratify the reality of trance as an altered state.

Trance Reinduced by Catalepsy

[The senior author reaches over and gently touches the underside of her left hand. She

takes this cue, and her left hand lifts slowly. It remains suspended cataleptically in midair.]

E: Do you always leave your hand suspended in mid air when a stranger touches your hand?

X: Do they always?

E: Yes. Do they remain suspended in midair when a stranger touches them?

X: No, not usually.

E: All ways of going into a trance.

R: Your earlier posthypnotic suggestion to enter trance in all ways is now effective in reinducing trance by evoking a catalepsy of her hand.

Ratifying Trance: Demonstrating Unconscious Control over Behavior

E: Were you in a trance?

X: I guess so.

E: What makes you think so?
[Pause]

X: I was aware of not having control over my hands.

E: Who had control over them?

X: I don't know. It wasn't me. It seems like you did.

E: I don't know how to contract your muscles.

X: Maybe it didn't seem as if I have control.

E: Um hum. How can you develop another trance?

X: By recalling the same music?

E: All right. Now I'm not wasting your time, nor my own. I am laying a background for the development of your own conscious understanding. Now I am going to do something.

R: You ask these questions only after she has had enough evidence of unusual behavior so she must acknowledge that something in her experience is different: She experienced an altered state

that we now label as trance. You are achieving an important aspect of your hypnotherapeutic paradigm. You are demonstrating to her conscious mind that the unconscious can control her behavior. This tends to depotentiate her habitual, everyday frames of reference. Your questions are directed to helping her realize that her ego is limited in its control, but her unconscious has potential for control and eventually cure.

E: Her response, I don't know. It wasn't me, is clear proof to her and the observers.

R: By asking her how she can develop another trance you are by implication labeling her previous experience as trance. She acknowledges your ratification of her trance when she then suggests she can develop a trance by recalling music again. In a very subtle and indirect manner she comes to accept her experience as a genuine trance in a way that bypasses any critical doubts she may have had. With your final statement about the development of her unconscious understanding you again emphasize the importance of the unconscious and heighten her expectancy of what is to come.

E: Yes.

Trance Reinduction by a Question: Initiating an Unconscious Search

E: Do you know that you will be in a deep trance when I touch your face? [The senior author touches his hand to her face. She closes her eyes and remains immobile.] Now rest very quietly. And enjoyably.

R: You are again making use of your earlier posthypnotic suggestion that she could go into trance all ways. This time you reinduce trance by suggesting a cue [touching her face] in the form of a question. Such question inductions are particularly effective because questions are a marvelous means of fixing and focusing attention inward. In this case the question obviously initiated an unconscious search and the requisite unconscious process to lead to the desired hypnotic response of trance. One of your most effective forms of hypnotic suggestion is to ask questions that cannot be answered by the patient's ordinary conscious frames of reference. Questions that ask for an autonomous response [such as ideomotor signaling] on an unconscious level usually depotentiate consciousness and lead to trance experience.

Assigning the Locus of Therapeutic Change as Taking Place in the Unconscious

E: And you're beginning to understand that your unconscious mind can develop control and take charge of so many things. Now in awakening I want you to do it easily and comfortably in your own way.

R: You are again emphasizing and demonstrating unconscious control over behavior and making direct statements about it, so she will have a clear understanding of it as the means of your therapeutic approach.

E: I say so many things to emphasize the plural.

R: That implies the unconscious can also take control over her symptom, too.

Two-Level Communication

E: In a way that meets your *needs.* But I want your unconscious mind to continue to listen to me and to understand what I say even though your conscious mind may hear something different. Now take it easily and awaken. [Two-minute pause] Now. [Long pause for at least five minutes during which X does not awaken. The fingers of her left hand move as if playing the harp, she grimaces and frowns and has the appearance of being in a state of intense inner concentration.]

E: The plural here again with meets your needs. I'm actually talking about two-level communication without really explaining it.

R: That opens the way for two-level communication? E: That tells her I am talking on two levels.

R: That the conscious mind can understand one thing while the unconscious can elaborate many other associations. The unconscious can elaborate whatever associations are necessary and pertinent to her particular problem. You are again using general words that can be interpreted in as many different specific and personal ways as possible relevant to particular problems. The success of this approach is suggested by the fact that her inner absorption was so deep at this point that it took her at least seven minutes to awaken. The activity of her face indicates that inner work was certainly being done. She was not asleep!

Unconscious Work During Trance: Unconscious Problem-Solving

E: Go right ahead [Pause] and share that with your conscious mind. [Another long pause as X remains in intense concentration] Share it with your conscious mind. [Another long pause] This struggle is helping you. Even though you don't know consciously all of the struggle, that is all right.

R: This was a relatively rare instance when a subject did not awaken immediately after you gave suggestions to awaken.

E: Her unconscious mind understood something different from the word awaken. What does awaken mean? Wake up to your opportunities!

R: Wake up to your opportunity to do inner work?

E: When the *hell* are you going to wake up? is common folk language.

R: That is folk language for: When are you going to realize what is happening to you?

E: I told her to look for the double meaning, and her unconscious is doing that.

R: That is a double bind: You are forcing her to work on an unconscious level even though she cannot recognize it on a conscious level.

E: Yes. I set her up to place unconscious understandings on whatever I say. *They will be her unconscious understandings.*

R: This is beautiful! No matter what the problem is, no matter what the therapist's hypotheses are, you are encouraging the patient to do her own work, inner work that is valid for her unconscious.

E: She is not limited or biased by my ideas.

R: So this is a most general way of facilitating problem-solving.

E: *I don't need to know what your problem is for you to correct it*.

R: Valid hypnotherapy can be done without either the patient or therapist knowing what the problem was.

E: That's right. Note the strategy here of the pause after Go right ahead," and then the longer pauses. That means there is no hurry, it can take place today, tomorrow, sometime. Do it at your leisure, in other words. Only you haven't said, Do it at your leisure. But that is the understanding the patient gets.

E: It allows the patient to relax so inner work can be done.

E: I'm telling her it is a struggle. Then I give reassurance with that's all right about something about which she knows nothing.

Therapeutic Trance as Intense Inner Work

E: [Another long pause as the intense inner concentration with wrinkled brow, frowning, and taut face continues.]

Now you can leave the struggle at this point. But you can return to this point. And there can be an interlude of conscious awareness. You can come right back to this point any time.

R: Is more effective therapy done when a patient is obviously engaged in intense inner concentration, as is the case here, or when the patient appears more relaxed, passive, and asleep? What state do you prefer in doing therapeutic work?

E: I like to see this that we see in Miss X.

R: This is the more effective type of trance for doing inner work. Since she was frowning, did she have a conscious awareness of what was going on within her?

E: She knew she was doing some thinking, but she didn't know what it was. [The senior author gives analogous instances where certain wire puzzles can frequently be solved by taking them apart behind one's back or with eyes closed because visual interference with kinesthetic cues is eliminated. In a similar manner many emotional problems can be solved more easily without conscious thinking.] I tell her she can leave the struggle because she does not have to fight that battle every day, every night. She can always return and fight another day.

R: Here you carefully break into whatever inner work was being done and let her know she can return to it after an interlude of conscious awareness. This is another form of posthypnotic suggestion that assures that she will return to trance and continue her important inner work when you give the signal.

Two-Level Communication and Trance Depth

E: On my signal? And I am going to ask you *now,* and I mean to awaken. Right *now!* [X finally opens her eyes] You want to tell me anything? [Pause as she continues awakening by reorienting to her body.]

X: Did you say things that I didn't hear?

E: That is an interesting question. Why do you ask that? [Pause]

X: I don't know. I just have the feeling that you were talking to me, or somebody was, and I couldn't hear.

E: Who was talking to you? Take a guess. [Pause]

X: I don't know.

E: It was someone you knew, and everybody here is a stranger.

X: Was it somebody new or I knew? Did you say, or was it a stranger?

E: Everybody here is a stranger. Somebody you knew? Can you tell us? [Pause]

X: It must be me. I can't think of who else it would be.

E: Someone you know very well. There is a bond between you. Do you want to disclose that?

X: I'm shaking my head no, but I don't know if I could disclose it.

E: Do you know who the person is? [Pause] Your unconscious doesn't want your conscious mind to know.

X: That is why I can't tell you?

E: Um hum.

E: Who is the someone else? She has a sexual problem. Another person is involved.

R: Her three-year followup proves you were correct in your assumption that there was someone else involved. How did you know, since she gave you no hints of it in your interview thus far?

E: Someone else in that context could be a real person or another part of her personality. X came in. I got the least possible amount of information, knowledge, to understand something. Then I improvised thereafter. But I knew what I was doing. I laid each step carefully. I planned to say the word music, and I planned to return to it.

R: Yes, to produce a structured amnesia.

E: I implied sex, and then I returned with there is someone else.

R: You continued with the sexual theme.

E: But I said there is someone else to you, not to her!

R: That made it a more potent indirect suggestion. That is how you use an audience, to give indirect suggestions to a patient. Under the pretense of giving a didactic lecture on hypnosis, you are actually administering indirect suggestions.

E: That's right. If I don't have an audience present, I can elicit some memory of hers and make a few remarks about that harmless memory. And that is my audience. I can comment on her trip to Chicago, which has nothing to do with the problem at hand, but in commenting on that trip I can put in double meanings.

R: The audience is actually another pattern of associations in her mind. This is another way of talking on two levels.

Conscious and Unconscious Head Signaling: The Unconscious Personality

[X shakes her head no in an absentminded manner.]

E: And there was an I don't know head movement confirmed. Now I am talking to someone else, and she doesn't know to

whom, only I know. [To the audience] Wasn't that beautiful?

E: Now when she shakes her head, that was an absentminded withdrawal to a trance state. If you recall, she was shaking it no very slowly.

R: A very slow head movement is from the unconscious, while a fast head movement is from the conscious.

E: Yes, and the unconscious response comes after a delay, while the conscious response comes immediately. I'm talking to her unconscious personality.

R: In talking to someone else, her unconscious personality, you are further depotentiating her everyday frames of reference about herself so that an unconscious search is initiated for this other aspect of her personality. This is, of course, an excellent approach for evoking multiple personalities or more repressed aspects of one's personality.

Facilitating Amnesia: Working with Associations

E: And now where were you born?

X: Arizona

E: How long have you been in Memphis?

X: Nine Years.

E: And doing social work, where?

X: St. Joseph's Home for Children.

E: There is a child guidance clinic somewhere in Memphis.

X: Yes.

E: My name ever been mentioned there?

X: Would your name ever be mentioned there?

E: Has it been?

E: On my signal? answers the patient's inner questions, Should he alone signal me, or can I signal myself?

R: Her questions about not hearing or who was speaking are very interesting. Would you say her remarks are an indication of deep trance in spite of all the other indications of tension and frowning, etc.?

E: Yes.

R: Does her remark about not hearing prove her consciousness was depotentiated since she has

no conscious awareness of what you said?

E: That's right. I did effectively talk on two levels.

Hypnotic Amnesia

E: What do you suppose was said? [Pause]

X: I don't know.

E: All right. Without looking, what time do you think it is?

X: Around 1:00.

R: About quarter to one. [Pause]

R: Is she experiencing an amnesia, or was she so deep in trance that she just was not receiving, simply did not hear or record what you said even on an unconscious level?

E: She is saying, I, the conscious me, does not know.

R: How would you prove that? You could ask for ideomotor signals from the unconscious to determine if it was receiving things the conscious mind could not recall.

E: Yes.

Variation in Trance Depth: Therapeutic Suggestions Bridging Conscious and Unconscious

E: How deeply in a trance were you?

X: How can you tell?

E: What do you think is all I want to know. [Pause]

X: Like how well done is the steak - medium to deep or medium to well done?

E: [To R] She illustrates very nicely how a second trance very greatly deepened. And she further illustrates the wealth of activity that is really cut off from her conscious knowledge.

R: I have had the difficulty of putting people so deeply into a passive sort of trance that I am not sure they are receiving what I say even on an unconscious level because they do not respond to posthypnotic suggestions. How can I be sure patients are actually receiving what I say?

E: You can put people very deep, but you talk so there are islands which they can use as a

highway. They are on the bottom of the deep ocean. They need to come up and jump from this island to the next.

R: There are variations in trance depth from deep ocean to conscious island that you utilize to give suggestions.

E: You say something they can hear in deep trance that they can relate to consciously. For example, a bit earlier I said, And there, can be an interlude of conscious awareness.

R: That suggestion brought up an island of conscious awareness?

E: Yes, something that can be seized upon.

R: How does that help them follow a posthypnotic suggestion? It raises them momentarily to consciousness where they can receive the suggestion?

E: It leads into consciousness.

R: Are you building an associative bridge from the unconscious to the conscious?

E: Yes, it builds a bridge between the struggle taking place on both conscious and unconscious levels.

R: In deep trance it is possible to place suggestions so deeply that there is no bridge to consciousness where they can be expressed. Those suggestions cannot be therapeutically effective.

E: That is why I build bridges.

Two-Level Communication Utilizing an Audience or Memories

E: [To RJ] And there were thoughts of someone else, and very sensitive thoughts. Now shall I continue describing what I saw: [To X]

X: I don't know. I am only familiar with it by name. I have never been there. I have been inside, but I am not really familiar with it.

E: I lectured there a number of years ago. Now I am engaged in social chitchat for the passage of time.

X: I was just thinking that.

E: With that first question she is back at an infancy level. [The senior author gives personal examples illustrating how such questions invariably evoke important early memories and associations.] When you ask, Where were you born? you are really massively changing the train of

conversation. You are massively augmenting any amnesias. I'm taking her far back to Memphis, far from this room, thus augmenting amnesias for what has happened here. Then, by having her search her Memphis memories about whether my name was mentioned there, I'm keeping her in Memphis.

R: This clearly illustrates how you are always working with the patient's associative process - putting it here and there. You appear to be making casual conversation, but you are actually doing something with the patient all the time.

E: Then I identify what I'm doing as social chitchat. I was just thinking that she was an intelligent girl.

R: So you acknowledge her intelligence by telling her what you are doing.

Training for Deeper Trance

E: [To R] Now you are witnessing that training for a deeper and deeper trance.

R: What do you mean by your remark about deep trance training?

E: You've just seen me waltz her from Phoenix to Memphis. Now I've waltzed her back with this remark to you! When she says, I was just thinking that, she is really talking on two levels. She is the observer. I've waltzed her from being on the subjective [immersed in her subjective memories of Memphis] to being the observer.

R: Why is that training for deeper trance?

E: When you can waltz a person about like that from Phoenix to Memphis, from subjective to objective, you have changed her whereabouts and status very simply.

R: That is training her for deeper trance in the sense that you are training her to follow you? Anything that causes the patient to follow the therapist, or any approach that enables the therapist to change the patient's mental status, is training for deeper trance?

E: Yes.

R: This has nothing to do with the trance state per se; it is the skill with which the therapist changes the patient's associative processes. This is a basic skill any therapist should have quite apart from any use of hypnosis.

E: That's right.

Ratifying Trance and Two-Level Communication

E: And you are witnessing the training for a two-level communication. [Pause]

E: As I say this to you, she is also being the observer, since she is being talked about. It reinforces what happened before.

R: By talking about training for a deeper and deeper trance," you are ratifying the fact that she has experienced some trance. With this remark about two-level communication you are ratifying that two-level communication has taken place. But why?

E: Because I don't want her unconscious mind to ever think, He didn't mean those sexual allusions.

R: You are ratifying the two-level communication.

E: And it can be related to this waltzing from Phoenix to Memphis and back to Phoenix. And from patient to observer.

R: Her three-year follow-up does indicate that the changes from Phoenix to Memphis are related to the someone else and the sexual problem alluded to in your two-level communication. It is hard to believe that you were not using some form of ESP.

E: I had no way of knowing that, but I can suspect it with my knowledge of human beings.

Questioning for Unconscious Ideomotor Head Signaling

E: Now do you mind thinking, just thinking about something highly emotional?

X: Thinking about?

E: Um hum. Now, my question was, Do you mind thinking about a highly emotional matter?

X: A highly emotional what?

E: Matter.

[X's head bobs about uncertainly and apparently absentmindedly.]

E: And your head movements were not really understandable. In response to my question, Do you mind thinking about a highly emotional matter? your head moves yes, no, I don't know, maybe.

X: That's right.

E: May I ask you to think of a highly emotional matter?

X: Anything in particular?

E: [To R] We will just discuss that. I ask a specific question, and she said, anything in particular? Now what does that mean? There are some things that she chooses not to talk about, not to think about, and some she can. [To X] You see, I don't need to know them. But you need to know them.

X: I'd rather you knew them.

E: You'd rather I knew them?

[To R] Well, I didn't ask her to confide in me, but the effect is what?

R: She would rather you know.

E: She told me she was willing to confide in me. That is much better than pressing a patient to give you information. I'm explaining a technique of dealing with patients. And let them have every right that they ought to have. The main purpose is to help the patient. Not to satisfy one's *curiosity.* And I was just showing, illustrating, the way one puts questions that gives the patient the right to choose whether or not to confide.

[To X] How do you feel about my using you for a demonstration? [Long pause]

E: These are soldering questions. In the previous trance there were sexual allusions. Now I'm getting in the words highly emotional.

R: You are now binding sexual allusions to highly emotional.

E: Then I reassure her that I don't know.

R: That is characteristic of your approach. You build up high tension with some provocative remarks that send the patient on some frantic unconscious search, and then you reassure and lower tension so that the unconscious process thus initiated can proceed in peace on its own.

E: When I ask a *specific* question and she responds with anything in particular? she is indicating that there is a *particular* thing.

R: But evidently she does not want to reveal it.

E: Then I reassure her again with, I don't need to know them.

R: And you put the responsibility on her by saying, But you need to know them.

Dissociation and Rapport

X: I guess I feel kind of, sort of separate, even though it doesn't bother me that I am aware of.

E: No, you and I are together, and those people are outside. It is a very nice way of illustrating that we are here and [To R] you fellows are over there.

R: Yes.

E: And you did that so nicely, [To R] and I didn't tell her to do that.

R: Her sense of separation is a form of dissociation which indicates she has a separate and different relation with you than the observers? She has a special rapport with you that tends to exclude others.

E: Yes.

Facilitating Hypnotic Phenomena: Double Bind and Questions to Evoke Immobility and Caudal Anesthesia

E: Now I am going to say something to you. You are not going to understand it consciously. Doesn't it surprise you that you can't stand up? [Pause as X looks surprised]

X: Can I try?

E: Oh, you could *try.*

[Pause as X makes a slight forward movement in her chair with the upper part of her body only and then stops] It does surprise you, doesn't it? Some day when you get *married and are having a baby,* you can use the same measure.

X: Oh, really?

E: Um hum. I just gave you a caudal anesthesia or a spinal anesthesia.

X: [Nervous laughter]

E: *I don't lay on hands, I lay on ideas.* That is kind of a surprise to know that you can't stand up.

X: Let me know when I can.

E: I will always let you know when you can't. I'll always let you know when you can. [To audience] Now when a caudal anesthesia like that can be induced, you know you've got a perfectly good subject.

R: It is a beautiful double bind when you say you are going to say something to her that she is not going to understand consciously: She is bound to listen, but since she cannot understand consciously, she must respond on an unconscious level.

E: Yes.

R: You initiate a hypnotic phenomenon with a question. It is usually better to evoke a hypnotic phenomenon with a question than a direct suggestion? It is a fail-safe approach.

E: Yes.

R: What cues do you use to know when to attempt such a question to initiate a hypnotic phenomenon?

E: You always give praise to the unconscious.

R: Just previous to this question you did give her unconscious praise when you remarked, And you did that so nicely, and I didn't tell her to do that. The way you say the word try with a subtle, dubious tone in your voice implies she can try but will fail.

E: Yes.

R: Were there any other cues you used to know when to evoke this immobility? Did you notice that she was already manifesting signs of being in a trance, slow eyelid movements, etc. ?

E: I praised her unconscious, and if she has picked up some sexual allusions, I can be pretty sure the sexual allusions here [getting married, having a baby] will be involved.

R: So you suggest a hypnotic phenomenon where she can be involved. That is why you used this hypnotic phenomenon rather than something else?

E: Yes, it was a specific application for her.

R: Because you were building up sexual associations.

E: I needed to see if I could confirm it.

R: Since she succeeded in experiencing this hypnotic phenomenon, would you take it as a confirmation that your sexual associations were picked up?

E: Yes, with a minimum of words I induced a spinal anesthesia. If I was right in all my double-talk, she is going to develop caudal anesthesia. Since she has studied [a medical specialty], she knows what a caudal anesthesia is. I'm literally asking her, Does my talk on two levels about sex have meaning? She says, It did. No direct words have been said. Nobody listening can know it. But her unconscious and I can know it.

R: So you have been preparing her for some time to experience this hypnotic phenomenon of caudal anesthesia. It is not just a casual intrusion. This reminds me of your preparation for having a patient experience visual hallucinations: You usually activate many trains of association regarding the subject of the hallucination before you try to evoke it.

E: Yes. *Hypnotic technique is giving the stimuli that can be resolved by the subject into the hypnotic experience you wish her to have.*

Depotentiating the Clinical Problem

E: And the next question is she's got a definite and limited problem. And that has interfered with her as a personality very much. Now is that personal problem a serious emotional problem, or is it a superficial emotional problem? I can think of a serious case of claustrophobia. The solution was somebody walking rapidly across the floor and down the steps, clicking her shoes at each step. When she was a little girl, her mother punished her by putting her in the closet and then walking noisily out of the house and down the steps.

R: Um. So really a very superficial thing.

E: A very superficial.

R: Not a deep emotional disturbance.

E: Not a deep emotional experience. Now your sweating may be caused by some superficial thing, or it may be a very dramatic thing. By the way, how many doctors have you seen about your sweating? [Pause]

X: All- told about ten. Ever since I was little, I asked every doctor I happened to run into.

E: And your sweating has been sufficient so you could hold your hands out allowing *a puddle to form on the floor.* Have you been able to let a puddle drip on the floor? Have you seen other doctors and did you puddle? How have you done here?

X: What?

E: How much sweating have you had here?

X: Oh, not a puddle.

E: Your hands were moist when you came in. But you haven't puddled.

R: In this section you limit and depotentiate the sweating symptom with direct remarks as well as clinical cases from your experience.

E: This was an actual case of claustrophobia.

R: You tell such actual cases to develop a positive expectancy in the patient.

E: When I tell her the sweating can have a superficial origin, I'm telling her that her sweating is

not the scary thing she thinks it is.

R: This is a way you depotentiate her previous rigid sets and fears about her problem.

E: What does a baby do?

R: Puddle on the floor. It has sexual associations when you talk about puddling on the floor?

E: Yes, I'm still keeping the sexual associations in there.

R: You continue to depotentiate her symptom frame of reference by downgrading it with your casual but concrete comments about how little sweating she's had here.

Puns to Initiate Unconscious Search and Creative Moments

E: To the last puddler I saw I said, You really are ambitious, you don't like the puddle you are in. It pays well. You hate to give up all that pay. As long as you can lead a band in Las Vegas, you will have puddles. You can give up Las Vegas. Go to New York. Live by yourself in an apartment. Write music and arrangements. You'll be free. A year later he was turning out a lot of music and arrangements and free of his puddling. Now you weren't embarrassed by my talking about you, were you?

R: You don't like the puddle you are in is actually a pun relating symptom (sweating) to personality problem (ambition). Such puns may seem funny and even superficial to some readers, yet in one stroke they can fixate a patient's attention, depotentiate erroneous frameworks, initiate an unconscious search, and facilitate *a creative moment* (Rossi, 1972b) wherein startling insight may be achieved.

Assigning the Unconscious as Locus of Therapeutic Change

X: I didn't know you were talking about me.

E: Have I talked about you? [Pause]

X: I think so.

E: You don't have to be concerned.

[Erickson now engages Miss X in a five-minute period of chitchat about her family and her general interests. He is apparently taking a break, allowing her to relax from the very intense period of trance work. Such alternations in the rhythm and intensity of conscious and unconscious work are important. There is a natural ninety-minute biorhythm of rest and activity, fantasy, intensity, and appetite that we all experience continuously (Kripke, 1974). It sometimes seems as if Erickson recognizes that natural variation in the patient's biological clock and adjusts his rhythm of alternating trance and conscious work to

coincide with it.]

E: She ought to think I've been talking about her. She really has got a lot of amnesias when she makes remarks like, I didn't know you were talking about me.

R: In other words, her conscious mind is confused here, and as a result she is open to therapeutic work on an unconscious level since her conscious limitations are in disarray.

E: She doesn't have to be concerned since her unconscious does all the listening.

R: That is right, you are giving potency to her unconscious because that is where the important work is going to be done.

SESSION ONE

Part Three: Evaluation and Ratification of Therapeutic Change

In the previous section the senior author continued structuring the conscious-unconscious double bind and his two-level communication approach. He assigned the locus of therapeutic change to the unconscious and let the patient have a very intense trance experience during which therapeutic change could take place. He depotentiates her symptom and then notes that she has not, in fact, been manifesting her symptom during this session. The entire procedure has been so casual that she does not yet realize consciously just how much therapy has been taking place. The stage is therefore set for an evaluation and ratification of the therapeutic change.

Demonstrating a Therapeutic Change: The Double Bind in Try Related to Hemispheric Specialization

E: Do you think you could make a puddle with your hands now? Try it.

X: Try? I did make a puddle for some doctors once. This doctor told me it was the worst he had ever seen and he went and got a bowl. Four other doctors came around to watch me make a puddle.
[X places her hand in position to create a puddle, but no significant moisture appears.]

E: I said *try* it! You are beginning to have some doubts?

X: About a puddle, yeah. I could give you a little stream.

E: Try it. Just a little puddling stream.

[Pause]

Looks like your poorest performance on the record.

X: I can't understand it.

R: Right after a short period of chitchat you ask a very challenging question to demonstrate a therapeutic change: Her sweating has decreased.

E: I said, try it, implying she is to make an effort and at the same time to negate it.

R: You had her in a double bind, didn't you?

E: Yes.

R: The word try evokes a double bind situation when it is said with the appropriate inflection and dubious tone of voice. The word try means make an effort. The dubious tone of voice says, Do not succeed in that effort. She is thus placed in a bind where nothing happens. Even the symptom is turned off. I sometimes wonder if such double binds that function in two modalities are related to the differences in cerebral hemispheric functioning (Diamond and Beaumont, 1974; Rossi, 1977). The cognitive meaning of try would be processed by the left hemisphere, while the emotionally laden tone in which it is said would certainly be processed by the right hemisphere. Since psychosomatic symptoms are now thought to be mediated primarily by the right hemisphere (Galin, 1974), your negative tone pf voice would be able to block the symptom at its right hemispheric source. Much research certainly needs to be done in this area (e.g., Smith, Chu, and Edmonston, 1977).

When you next say try it with emphasis, you immediately double bind it with the negation, You are beginning to have some doubts. When you say try it the third time, you immediately double bind it with the joking tone with which you say just a little puddling stream and your poorest performance on the record. Her final response of not understanding why she does not experience the symptom indicates that her conscious mind is puzzled and rather depotentiated. It has been caught in the double bind that made her symptomatic behavior impossible, but she does not know why. It is important that consciousness be depotentiated when you challenge the symptom, since that allows it to drop into the unconscious which you have prepared as the locus of therapeutic change.

A Pun Associating Symptom Cure with Appropriate Psychodynamics

E: Do you suppose your hands are unfolding for you to become *a dried-up old maid?*

[Pause as X continues to try but with no success]

E: Who is a dried-up old maid? Someone without a sex life.

R: It is another pun to facilitate a creative moment:" dried-up" means symptom cure, and on another level it relates to sexual activity. Again you are tying symptom cure to a sexual association. You are not dealing with a simple symptom removal by direct suggestion. You are associating symptom cure with the appropriate psychodynamics that are related to it.

E: Old maid is the question.

R: Your question with a pun catches her attention on many levels; it associates symptom change with the appropriate sexual psychodynamics underlying the symptom and directs her unconscious to work on that association. Her follow-up letter does, in fact, indicate that she was well on her way to becoming a dried-up old maid if she did not deal decisively with her romantic life at this time. As her followup letter indicates, however, she was later able to deal effectively with her love life.

Depotentiating Conscious Doubts About Symptom Change: Depotentiating the Symptom

E: Discouraging, isn't it?
[Pause]

X: Yes it is.
[Pause with more futile trying]
Too bad we didn't have a harp here, so I could play.

E: Do you type?

X: A little bit.

E: Do your hands drip on the typewriter? [To R] Do you have a typewriter with you?

R: No, I don't, unfortunately.

E: Do you suppose if I got a typewriter for you, you could feel your fingers getting wetter? Do you really suppose you could?

X: I don't, I don't think they are going to get any wetter than this.
[Pause with more futile trying]
I don't know.

E: By saying, Discouraging, isn't it? I'm making light of it and depotentiating the symptom. When she says it's too bad we don't have a harp, it indicates that she is on my side now and wants to demonstrate symptom cure by actually playing the harp.

R: You then by implication generalize the symptom cure from harp to typewriter. It is important to demonstrate symptom cure concretely in the here and now.

E: Yes, and without reassurance. Reassurance only implies You can fail. If you say, You*can* get over this, that implies you have it.

Ideomotor Signaling to Ratify Symptom Cure: The First Round

E: Lifting your right hand means yes, lifting your left hand means no. Does your unconscious mind think that you can make a puddle with

your hands? Which one will lift? Wait and see.

[Pause]

You can even watch to see which one is going to lift.

X: I can watch?

E: Yes.

[Pause as her right hand lifts a bit, then her left hand lifts a bit too. She has been looking at her right hand.]

E: [To R] The fixation of her gaze shows her conscious action. She only shows one slight look at the other hand. We know what her conscious answer is. She doesn't know what her unconscious answer is. [To X] But your unconscious will suddenly give you a correct answer. [Her right hand lifts more strongly.]

R: You are now using ideomotor signaling as a further demonstration of symptom cure? You are trying to eliminate any further doubts about her symptom cure?

E: Yes, and I create a state of uncertainty by asking, Which one will lift?

R: That uncertainty tends to depotentiate her conscious (and problematic) frames of reference so her unconscious has an opportunity to respond.

E: Where a person looks in finger or hand signaling indicates their conscious expectation.

R: If you have no concrete way of demonstrating symptom cure in the therapy situation itself, then this sort of ideomotor signaling is a good substitute (Cheek and LeCron, 1968). She finally lifts her right hand more strongly, indicating that her unconscious believes she can puddle her hands. Yet she cannot actually do it. How do you explain this discrepancy?

E: She knows from long experience that she can puddle. I haven't taken anything away from her.

R: By lifting both hands she is saying that you haven't taken anything (her symptom) away from her; the capacity for the sympton is still there.

E: Yes, the capacity is there, but there is no longer fear.

Depotentiating Conscious Doubts About Symptom Cure: The Double Bind

E: And now you are seeing a demonstration of what it means when people say it is hard to believe. All past experiences made only one answer

possible. But the unconscious is going to give a forcible answer.

[Pause]

It is difficult to change one's set frame of reference.

[Pause]

And you are afraid to know the answer.

[Pause]

It is perfectly all right to think one thing consciously and to know exactly the opposite unconsciously.

[Pause]

And does it put a strain upon you? And yet there is no sweating in spite of the strain. So now you will have more courage.

[Pause]

That really takes a great deal of courage.

E: I'm using folk language to express what people feel.

R: It is hard for a patient to really believe a long-term symptom can disappear so quickly. By giving voice to this inner doubt you are depotentiating it.

E: Yes. It is difficult to believe these changes have been made.

R: She is afraid to know the change has really been made, lest she be disappointed.

E: That's right.

R: Here you are allowing room for conscious doubts, but reinforcing the fact that the unconscious recognizes there has been symptom change. This is another use of the conscious-unconscious double bind. Then, even though the ideomotor signal of the right hand lifting means she still has the capacity for sweating, you point out that at present there is no sweating in spite of the strain. You then give strong ego support for the courage to believe, but you don't actually say believe, since that would imply doubt.

Posthypnotic Suggestion

E: I am going to ask you to awaken, and I'm going to tell you an apparently meaningless story. But your unconscious mind will understand. Now awaken now. one, two, etc. to twenty, nineteen, eighteen, seventeen, sixteen, fifteen, thirteen,

nine, eight, seven, six, five, four, three, two, one. Awaken.

R: This is an interesting form of posthypnotic suggestion whereby you are able to later give her unconscious a message that will not be meaningful to her conscious mind. In this way you may be able to bypass the limitations or doubts the conscious mind may have.

Until : Posthypnotic Suggestion for a Continuation of Psychotherapeutic Work on Symptom Cure

E: You know the comic strip of Mutt and Jeff? Do you know them?

X: Yes.

E: One day Jeff was searching his pockets desperately, and Mutt was watching. Over and over again Jeff searched his pockets. And

Mutt asked him why. And he said, I lost my wallet and I looked in all my pockets except one. I can't find it. And Mutt asked him, Why don't

you look in that one? Jeff answered, Because if it ain't there, I'll drop dead.

[Pause]

When did you decide I would be the last hope?

X: I know my unconscious knows what that story means.

R: This is one of your favorite anecdotes to deal with the patients' conscious doubts about symptom cure. You depotentiate their conscious doubts with bits of humor and simple acknowledgment of the doubt.

E: Yes, that is a perfect example. I've also said to patients, And you are going to doubt it all the way home until.

R: Why do you end the sentence with until?

E: Now you want to know the end of the sentence, don't you? The patients who doubt symptom removal will doubt all the way home, and then they start looking for the until. Until something happens, you see. They start looking for what it is that will tell me that it is gone. They are

expecting.

R: You have them looking for and expecting a confirmation of symptom cure.

E: Yes, I'm setting them up for that.

R: So when the patient walks out of the office he is still doing psychotherapeutic work. This is a form of posthypnotic suggestion to search for convincing proof of symptom removal.

E: All the way home until they know.

Ratifying Symptom Change

E: And when did you decide I was your last hope?

[Pause]

X: When I was reading this book [Haley's *Uncommon Therapy.*]

E: As soon as I get shut of you, the better.

X: As soon as what?

E: I get shut of you, get rid of you, the better, which isn't complimentary, is it ? Or is it?

[Pause]

X: You mean complimentary to you?

E: To you.

X: To me. Oh! Yeah, I guess I do have a feeling that, yeah.

E: The sooner I can get rid of you, the happier I'll be and the happier you'll be. Which raises the question in my mind, when do you leave?

X: Saturday afternoon, late.

E: How are you travelling to California?

X: Flying.

E: Did you do any puddling on the plane?

X: I don't think actual puddles, but some streams.

E: And you came in here with only a faint mist.

X: Yes.

E: This question reinforces her hope and makes it real in another way. I was her last hope. I was *her reality* hope; I was a hope made into a reality. I'm ratifying her hope and making it real.

R: Your question then was another way of ratifying that we have done our therapeutic hope. Such remarks made in a humorous vein tend to speed up the therapeutic process and further ratify that therapy is being done.

E: I'm derogating the symptom as a way of depotentiating it with my comment about only a faint mist.

Indirect Posthypnotic Suggestion via a Momentary Common Everyday Trance

E: Holding onto me, aren't you?

How soon will you forget me?

X: To be perfectly honest, I don't think I will.

E: To hold onto me means keeping me in some way; it means keeping what I did for her, not literally keeping me. Holding onto me, aren't you? and How soon will you forget me? are both posthypnotic suggestions. Forget me and holding onto me are two opposite things. Holding onto me is holding onto therapy. Forgetting me is forgetting me personally.

R: The careful apposition of opposites is one of your ways of focusing behavior, but what makes them posthypnotic suggestions?

E: They are questions; they fixate attention and call upon thoughts and associations that are inevitable in her future.

R: Fixating attention and initiating an unconscious search within define those questions as hypnotic. Even without inducing trance in a lengthy and formal way, you can so fixate attention with a question that you initiate a momentary form of the common everyday trance. Since she will inevitably have thoughts about her therapy with you in the future, these questions will tend to bind her future associations to this moment in therapy when you are actively depotentiating her symptom.

Distraction to Protect Suggestions

E: [To R] And how do you like that for a posthypnotic suggestion?

[Pause]

[To X] How do you like this kind of therapy?

X: I don't like any kind of therapy. You mean to do it or be on the other end?

E: How do you like my way of doing therapy?

X: I like your way.

E: And you promise not to forget it.

X: Um hum.

E: [To R] Reinforcing the posthypnotic but it certainly doesn't look like it or sound like it.

[To X] Now why do you insist on referring to past streams?

X: The past?

E: Streaming in the past.

X: You mean streams instead of puddles?

E: Um hum.

X: Two things I think. I guess I object to the word. The other thing is that mist, stream, or puddles, they are all just as bad for me.

E: Here I am defining it as posthypnotic to have more effect on her at the conscious level. With an altered tone of voice this question about this kind of therapy now makes the situation a personal kind of thing and a friendly relationship.

R: You are also immediately distracting her from the posthypnotic suggestions you have just given, lest her conscious mind starts to argue or interfere with them. This is highly characteristic of your approach - you make a suggestion and then immediately distract before consciousness can take issue with it.

E: My remark, And promise not to forget it refers back to my earlier question, How soon will you forget me?

R: That tends to reinforce the earlier suggestion while structuring an amnesia for all that took place between the two statements.

Depotentiating Conscious Doubts About Symptom Cure with Dramatic

Hypnotic Experience

X: I am aware of wanting to get rid of it, but on the other hand I guess I feel hopeless about it, about being able to change.

E: I know that. You also hope you will always be able to stand up, don't you?

X: Yes.

E: And before you met me, you believed that you could always stand up, and you found out that there are times when you can't stand up. Just try it.

[Pause as X again tries unsuccessfully to stand up]

You can do anything I tell you to do, can't you?

X: It seems like it.

E: Then you can stand up.

X: Can I?

E: Yes.

[She does stand up]

X: Yep.

E: Stand up again.

[While she is standing, the senior author continues as follows]

***Try* to sit down.**

[She stands with knees slightly bent but immobilized, and she cannot sit down]

[Pause]

X: I think my legs are made out of steel.

E: Now you can sit down.

[She sits down.]

Now do you know that you can do anything that I tell you to do?

Do you suppose that comes to having dry hands?

X: Could you make me have dry hands?

E: Um hum.

X: Maybe you can.

E: *Maybe?* What is your relationship with this fellow that came in with you?

X: I'm not sure.

E: I'm allowing her to express her hopelessness, then I proceed to demolish it with this demonstration.

R: You use a dramatic hypnotic experience (not being able to stand up) to depotentiate her negative, doubting, conscious framework of hopelessness about being able to give up her long-standing symptom. That is a major purpose in evoking hypnotic experience: to effectively demonstrate that something can change, to depotentiate the erroneous rigidities of a patient's conscious framework.

E: I demonstrate that there is something else besides her negative thoughts. It is further demolishment when she cannot sit down because she has known for a long time that she can stand up and she can sit down. I am not preventing her, it is a hypnotic experience: She is using something she didn't know she had. When she asks if I can make her hands dry, my um hum is not forceful but casual.

R: It is all the more convincing by being soft.

E: But I don't let her get away with maybe. I depotentiate it by repeating maybe? with a doubting tone and then immediately distract her from any remaining doubts by reference to her boyfriend.

Developing the Objective Observer

E: A longtime friend?

X: We were colleagues, not really. I guess you would say he is my boyfriend.

E: Do you mind if I ask him now?
[Erickson asks him a series of general information questions for a few moments, and then returns to Miss X as follows]
Tell me, any special thing that causes you stage fright or embarrassment?

X: My hands.

E: ***Now?***

X: Now? No, because we are talking about them.

E: I'm also still exploring the sex theme. I first let her define him. Then I let him define himself. This also allows her to sit back and see him objectively.

R: That develops the objective observer in the patient. Your incredulous response *Now?*again depotentiates the mental framework that makes her symptom possible.

Depotentiating the Symptom's Habitual Framework: Jokes and Unconscious Values

E: Let's remain silent. Then will they cause embarrassment?

X: No. Everybody in the room knows what my problem is, so I don't.

E: Is or was? [Pause]

X: Is.

E: Let's see those streams then.

X: They are just misty.

E: You couldn't irrigate anything with a mist. The only useful purpose for a mist is on the house plants.

X: But you can't play the harp with house plants either.

E: Therefore you reserve the mist for the house plants.
[Pause]
Struggling to believe is very difficult, isn't it?

R: Yes.

X: I have always had the feeling that if they could really dry up, it would never happen again.

E: Well, let's correct that.

E: Now we are transforming the symptom to the situation of talking about her hands. I am shifting the cause of the symptom: before, harp playing caused the symptom; now, talking causes it.

R: This is another way of gaining control over the symptom and depotentiating it: You take the symptom out of its usual context and shift it to a new framework where you can deal with it more easily - in this case simply by using silence. You then successfully challenge the symptom, and she finds she can only produce a mist.

E: I'm not abolishing the mist, I'm giving that mist a value removed from the harp.

R: You are displacing the symptom from a disturbing place to a useful one. The conscious mind may take your remark about the usefulness of mist to plants as a kind of absurd joke in this context, but you are accomplishing something very important on the unconscious level. For the unconscious, symptoms have an important value. You are letting the unconscious retain the value of the symptom (now diminished to a mist) by displacing that value to another concrete function: A mist is good for house plants. This kind of displacement works in the literal and concrete unconscious, even though it is absurd from a conscious rational frame of reference.

Reversals, Implications, and the Positive Values Inherent in Symptoms

E: Your hands can dry up, but do you want them to have the freedom to get wet again? Isn't that right?

X: Um hum.

E: Wet not only from putting them in water but by perspiration.
So don't try to rob your hands of rightful perspiration.
[Pause]
Your hands have been overperspiring for a long time.
Let's give them at least two hours to learn the right amount. And you canalready see that they have been doing a lot of learning.
[Long pause]

R: Is it a double bind when you ask if she wants the freedom to let her hands get wet again? It is a peculiar reversal when you tell her she can get wet hands.

E: I'm giving her freedom - even to get wet hands!

R: But if she is free to get wet hands, that must imply she has dry hands. So you've used implication to give her a suggestion for dry hands.

E: Since there is no restriction on wet hands, it also means there is no restriction on dry hands. She is not put into any rigid situation - there are situations where wet hands are acceptable. Until she met me, all wet hands were horrifying.

R: You are giving a positive value to something that was all negative before. You are helping her recognize the positive value of the physiological function that was formerly only a negative symptom.

Depotentiating Future Resistance: Being in a Trance Without Knowing It

E: By the way, how many times have you been in a trance today?

X: I was just trying to figure that out.
[Pause]
I don't know. I'm not sure.

E: More than once?

X: Yes.

E: More than twice:

X: Yes. I think so.

E: More than three times?

X: I'm not so sure.

E: More than four?

X: No, I don't think so.

E: More than five?

X: No.

E: Can you stand up?
[She stands.]

R: Why do you ask how many times she has been in trance today?

E: She cannot know for a certainty whether this idea came while she was awake or in a trance state. If you are going to hunt a deer, you had better know which field it is in, because you can't kill it in a field it is not in. She can't direct any resistance to any idea until she knows whether it was in trance or waking state.

R: So you are again depotentiating any possible expression of resistance here.

E: Future resistance! To resist any idea she first has to define it as trance or unconscious.

R: So you are making it difficult to determine whether the important suggestions were placed in the conscious or trance state. You are essentially using a confusion technique to protect your suggestions from her conscious resistance. Asking her this question about the number of times she

has been in trance can put her in a doubtful position about her unconsciousness. Thus it is very valuable therapeutically if patients do not know whether or not they were in trance. That confusion stops them from holding onto therapeutic suggestions in a way that allows them to repudiate them.

E: Yes, it is very valuable.

Hypnotic Immobility Conditioned to Try

E: *Try* to sit down.

X: I can't.

E: Are you in a trance?

X: I don't know.

E: You don't know.
That's right. You don't know.
That's why you don't know how many times you have been in a trance.
Now you can sit down.

[She sits down]

X: Oh, I see.

R: Being in a trance without knowing it?

E: Yes. If it were a boyfriend who told you you could not sit down, you would wonder if he was in his right mind, wouldn't you?

X: Yes.

R: Is this inability to sit down due to a momentary trance?

E: If I can put a trance in her hips, she has to recognize I can put a trance in her hands.

R: But why were you able to put it in her hips? She was in the normal awake state when you asked her the question.

E: 'Try to sit down.

R: The word *try* uttered in that soft and doubting way you have is a cue that she could not. You had conditioned her to immobility when you use the word *try*in that way.

E: Yes, the hypnotic response hits her hips or her hands, and she knows that. I have also gotten across the idea that she does not know whether she is in a trance or not.

R: What is your actual belief about being in or out of a trance without knowing it? If we had a machine that could detect trance, do you believe she would be going in and out of trance throughout the session?

E: Yes.

Dynamics of Indirect Suggestion: Demonstrating Unconscious Control of Behavior

E: And you are really becoming aware of how effectively your unconscious mind can control you.

R: All these demonstrations of the effectiveness of the unconscious to control behavior are to convince her conscious mind that her unconscious can also control her symptom? This is your basic approach to dealing with symptoms by hypnotherapy. You don't directly suggest symptoms out of existence. You arrange a series of experiences that demonstrate the potency of the patients' unconscious. You give them an opportunity to witness the therapeutic control their unconscious minds have over their symptom and then leave it to their unconscious to continue its therapeutic regulation. Therapy thus comes from an adjusted interplay of psychodynamics within patients rather than the patients trying to accommodate themselves to a therapist's direct suggestion from the outside. These are the actual dynamics of indirect suggestion.

E: Yes.

Open-Ended Suggestion to Cope with Problems

E: Now think of a few more of the things that you would like to have your unconscious take charge of.

X: Short of my hands?

E: Other than your hands.

[A comfortable chat now takes place about family matters and apparently unrelated topics for about ten minutes. He is giving her another rest.]

E: Here I'm getting at any other problems she may have.

R: This is an open-ended suggestion to let her unconscious resolve other problems the therapist may not even know about.

Ideomotor Signaling to Evaluate and Ratify Symptom Cure: The Second

Round

E: Now, before I asked you what your unconscious answer was about sweating, I told you about your hands.
Your right means yes, your left means no.
Yes'' you would have sweating, no that you would not have sweating. Watch your hands and see if they will signal yes or no.
Rest them on your thighs. Which is going to lift?

[After a minute or two of waiting, X's left hand begins to lift ever so slightly and very, very slowly with minor jerks.]

Your confidence is growing.
Growing more powerful.

[The right hand also begins to lift, but the left hand remains higher.]

You can close your eyes now.
Your unconscious can know the answer, but you don't have to know the answer. All right. Now drop your hands in your lap. The question has been answered. Now you can feel very rested and very comfortable. Now what is that smile for?

[Pause]

R: This is the second time you have utilized ideomotor signaling to ratify symptom cure. The first time she lifted her right hand, indicating she felt the symptom was still present. You therefore back up and do further work, (1) depotentiating her conscious doubts about symptom cure, and (2) depotentiating the habitual mental framework in which her symptom occurred. (3) You ratify your therapeutic work with various forms of indirect suggestion and protect these suggestions by distraction, etc. (4) You let her experience other dramatic hypnotic phenomena, such as being unable to stand up or sit down, to open other channels for therapeutic change that could bypass the erroneous symptom-producing structures of her ego. (5) You give her a breathing spell, and now you feel ready for another ideomotor test of the degree to which she is willing to give up her sweating. A change toward cure is evident, though the situation is still unclear: She does lift her left hand slightly, indicating the symptom is going, but then her right hand lifts, indicating it is still present to some degree.

E: The right hand lifting was a token answer for any remaining conscious doubts that she had.

R: This time the left hand lifts higher, indicating the answer has shifted more toward an acknowledgment of a significant symptom change. You then tell her to close her eyes and her conscious mind need not know the answer. Why?

E: [The senior author illustrates with a story indicating that the conscious mind interferes with therapeutic work.]

Ratification of Symptom Change

E: Those doubts come into your mind, don't they?

X: Yes, they do.

E: It is nice to watch growth.

R: Yes, absolutely.

E: Now I am going to tell you another story.

[The senior author now tells a clinical case history of how he helped an eleven-year-old control her bed-wetting. A major point of the case was that symptom control conies about gradually. He then continues.]

R: You now acknowledge her conscious doubts and bring them out into the open. You openly acknowledge the truth about her inner situation. She responds with an affirmative yes. You have thus also opened up a yes set. She is in an affirmative mood. You then immediately follow up with, It is nice to watch growth, which is a direct reinforcement of the fact that her left hand did go up, that she is changing and in the process of giving up the symptom.

E: With what part of the body does she wet?

R: Your story of the bed-wetter was particularly appropriate because the symptom of wetness and a number of details were similar. You are again bringing in sexual connotations.

E: Yes, wet genitals and wet hands.

Utilizing Time and Failure for Cure

E: Give yourself plenty of time. Now your hands have fizzled out for today. They can have some wetness tomorrow, the next day. And you will be surprised at the increase in length of dry times.

[Pause]

After a while you will have a drought on your hands. Now and then it rains

even in the desert.

R: You are utilizing time for symptom cure.

E: Yes, and giving her permission for failures. *All the failures will prove an improvement.*

R: The failures will prove the improvement because they come after increasing lengths of dry times.

Ideomotor Questioning to Ratify Symptom Cure: The Third Round

E: Drop your hands. Now let's see, which hand is going to move up. [The left hand lifts only. She frowns while it lifts.] The wrist, too. And the elbow will bend. Come toward your face. Higher, higher, up, well, that is really hard to believe, isn't it? That your unconscious says: Sweating is not for your future. And your unconscious knows that. Your unconscious knows that you will have a gradual growing conscious realization of that, that only at the speed that your conscious mind can tolerate. Close your eyes.

R: You test a third time, and finally only the left hand lifts, indicating that the sweating has been effectively dealt with. This is a clear case illustrating how you return again and again to deal with her doubts and internal resistance until you get a clear ideomotor response of symptom cure.

E: Yes.

R: You now extend the ideomotor response and, by implication, the cure by having her whole hand levitate higher and higher.

E: A gradual growing conscious realization means that she can learn as rapidly or as slowly as he wants to.

Trance Rest to Reinforce Therapeutic Change

E: Go deeply in trance. And now awaken at your convenience. (X closes her eyes, visibly relaxes for a few moments, and then awakens.)

R: After the successful ideomotor indication of symptom change you give her a period of trance rest. She had been under an evident strain (frowning) during the ideomotor signaling, so you now let her have a few moments of therapeutic trance as a way of rewarding her inner work with relaxation and inner freedom.

Humor to Facilitate Unconscious Psychodynamics

E: Now for a bit of flippancy.

X: Yes.

E: I embarrassed Dr. Bertha Rodger in New York. I was lecturing there at a banquet in my honor. Someone asked me where I was going to sleep that night. I said with Bertha. And I think you are very much surprised to find out how often you sleep with me. You are constantly going to sleep with me, aren't you? Rather shameless, aren't you?

X: No, I don't think I'm shameless.

E: It only seems as if I'm relating a personal narrative.

R: But in fact you are indirectly bringing sex in again. But what is the purpose of this direct sexual confrontation here?

E: I tell her she is going to sleep with me. Consciously she knows she is not.

R: She knows the absurdity of that.

E: But I have said it so convincingly. I have been very convincing to her unconscious so her unconscious says, He's not really talking about sleeping with him, he's talking about sleeping with someone else! I'm nakedly hammering on the sexual aspects.

R: You are using flippancy and humor to facilitate the inner resolution of the sexual psychodynamics of her problem. Humor depends for its effect on engaging unconscious processes. You use humor here to initiate an unconscious search and facilitate the unconscious processes intimately related to the psychodynamic source of her symptom reaction.

Ratifying Therapeutic Work

E: We *have* done a lot together, haven't we?

X: Yes.

E: We have done a lot together. You have been here two and a quarter hours. Do you believe me?

X: Yes.

E: Why, just because I said it?

X: No. I know that too.

E**: Now can you come back tomorrow? You have a lot of resting to do.**

X: Here or at home?

E: Preferably in Phoenix.

X: Do you want me to rest overnight so I can sleep with you again tomorrow?

E: Tomorrow because I want you to get some good phsysiological rest. You have done a lot of work. Far more than you know. You have altered a lot of your brain pathways.

You have set up new ones. You need to sleep. You are going to think about your hands in a different way.

R: You now directly help her acknowledge that a lot of therapeutic work has been done. You end this session with these marvelous waking suggestions that will facilitate conscious rest and further therapeutic work on an unconscious level throughout her sleep. Her attempt at extending your joke by asking, Do you want me to rest overnight so I can sleep with you again tomorrow? actually places sex where it belongs in the context of doing further therapeutic work with you; she is beginning to associate sexuality with therapy without quite realizing it.

SESSION TWO:

Insight and Working Through Related Problems

The next day X returned for another two-hour session with Erickson. Her friend L is present as an observer. The session begins with the spontaneous admission of her enduring feelings of confusion about yesterday's therapy. Such confusion is characteristic of the patient's mental state during the initial and middle stages of therapy with Erickson. Confusion is an indication that the patient's habitual frames of reference and generalized reality orientation have been loosened so that their psychodynamics are now in an unstable equilibrium. A process of deautomatization is taking place wherein many of the patient's erroneous sets that have been responsible for symptoms and maladaptive behavior are loosened to the point where new associations and mental frameworks can be formulated to achieve therapeutic goals.

Recognizing that a great deal of insight therapy needs to be done in this session, Erickson begins by giving her some mental warm-up exercises : He requests that she recall in exact detail the furniture of the place she slept the night before and then all the things she saw on a shopping tour yesterday. All of this may seem irrelevant to the patient, but Erickson is thereby warming up search operations in her mind with nonthreatening material. These search operations will be used later in the session, when she will need to seek and express insights.

The senior author then induces trance with an ideosensory approach (How soon will you warm up your hands?) that is uniquely suited to X because the sensation of warmth" is tied to the theme of sexuality that touches one of her basic unconscious complexes. He then embarks on the work of undoing repressions in a variety of ways. His object, as always, is to help the patient loosen the rigid mental frameworks that are responsible for symptom formation, so that the unconscious can restructure a better reality. He utilizes ideomotor signaling, analogies, stories, and other devices to move her associative processes continually toward introspection in critical areas. Here we witness Erickson at his best as a therapist facilitating the process of insight. He continually offers one approach after another, like a locksmith trying different keys until the patient finally unlocks her own repressions. After a great deal of initial resistance, X experiences a flood of insights about her family dynamics and the reasons for her symptoms.

The senior author then closes the interview and effectively terminates therapy by working through

many of her conscious doubts about symptom removal (her claustrophobia and fear of planes as well as sweating). In a respectful way he then finally discloses to X many of the therapeutic approaches he has used with her. The mysteries of hypnosis are dispelled with a simple statement of the Utilization Theory of Hypnotic Suggestion: He has only helped her utilize her own associations and mental processes to achieve her own therapeutic goals.

Confusion as a Prelude to Mental Reorganization

E: What have you done since yesterday?

X: Not very much. I went to bed relatively early. My mind seemed confused. I was recalling snatches of things that had been said, words mostly. Some of your stories. I didn't want to go to the bathroom in the middle of the night. I don't know if that had anything to do with what you were telling us yesterday, but I didn't want to go swimming last night either. I didn't want to go in the water. I just generally felt confused. I haven't been able to stop thinking about yesterday.

E: What particular thinking have you done?

X: Well, I'm kind of amazed at the feeling that there is sort of another entity inside that could listen and could understand things that I don't, and is maybe more hopeful than I am consciously.

E: Where are you staying?

X: With a social worker friend of mine in Tempee.

R: When she says, My mind seemed confused, you recognize it as a typical effect of the initial stage of your therapy. It is a good sign, since it means that her conscious frames of reference have been depotentiated and her unconscious has had an opportunity to reorganize itself along therapeutic pathways.

E: Yes.

R: Her conscious mind is confused, but since she has not been able to stop thinking about yesterday, it must mean that her unconscious has been very actively at work.

E: She feels there is sort of another entity inside, and then gives her prognosis.

R: Clearly indicating you have been on the right track in guiding her to make contact with this inner source that could understand more and be more optimistic than her conscious mind.

Training in Thorough Mental Examination

E: Name the items of furniture in the house.

X: Well, in the living room there are giant pillows instead of furniture, but there is a rocking chair there, too. There is a couch in the kitchen. There are tall bar stools in the kitchen. There are three bedrooms, so there are three beds. Two regular and one water bed. There are three dressers. I think that's all.

E: No other objects? You haven't named a table yet.

X: OK, there is a table and four chairs in the kitchen, etcetera.

E: Now, any special thing you did yesterday?

X: I went shopping by myself for about an hour and was sort of wandering around in a daze, just taking my time. Other than that, no.

E: Where did you shop?

X: A little place, well not little. It is a giant conglomerate department store.

E: What objects did you look at?

X: Food, cheese, meats, flour tortillas, wine, tomatoes, beans, *pants.*

E: Any other things?

X: No.

X: The pants that I bought were men's pants, but I looked at a pants suit that would be for a woman.

R: What's the purpose of this seemingly irrelevant question about house furniture?

E: When you think about a thing you think inclusively; don't exclude anything.

R: Oh, that's the implication! By having her think in extreme detail about her friend's house furniture, you are training her unconscious to go into something very thoroughly without telling her conscious mind what you are doing. You don't directly say, I want you to thoroughly explore your problems. Instead you put her through another task in a thorough manner. You then expect that process of thorough examination to automatically generalize to her own self-examination of her personal problems.

E: She came to me with a problem, and I tell her she is going to have to do some thinking. And then I demonstrate to her exactly the kind of thinking.

R: You then do the same thing by requesting she make a detailed examination of her shopping.

E: She makes a remarkable listing: she ends up with pants.

R: Oh, the sexual implication of pants?!

E: Yes! It is put in so beautifully. Why would she buy men's pants? It is like choosing a man.

Developing Insight

X: Once you asked me about how soon I would forget you. I didn't quite understand what you meant by that, but I think my response was that I didn't think I would, and L was giving bis explanation of what he thought it meant.

E: And what was his explanation?

X: Two parts of it, I think. One that I should not let you get in the way of me using myself or something. You are using yourself as sort of a metaphor to sort of assist me to do what I need to do for myself. Is that right?

E: He is sharper than a razor.

X: Yes, he is.

E: Anything else? [Pause] Only those things that you can say to the group.

X: Well, again I was surprised that it seemed as if my own conscious mind was a separate kind of thing, and I kept asking L if he thought that my unconscious could understand what my conscious mind couldn't. Then he sort of laughed and explained, of course, that would be true. Your use of the word courage sort of fit for me, partly because I think I found myself just recently overcoming a very difficult situation in my work by some sort of supreme exercise of my will and courage, too. I think. Oh, I know something else too. About the little girl with blond hair [X has blond hair and is here referring to a childhood memory] who was laying down on the stairs, and I think L said something about her having claustrophobia, and my response was, How does he know I have claustrophobia?

E: Do you really have claustrophobia?

X: Um hum.

E: How sure are you of that?

X: Well, I'm assuming that it is a matter of degree. Once when I was up in the arm of the Statue of Liberty, which is a very narrow passage, I blacked out because it was a very small area, and I don't like planes for the same reason. I always thought if somebody really wanted to torture me, all they had to do was to lock me in the closet.

E: Whereabouts in the plane do you have the strongest feelings?

X: When I am sitting by the window and look out. I guess that that is the worst.

E: How much plane traveling do you do?

X: I fly to the west coast about twice a year.

E: Now what kind of stores did you pass yesterday?

X: A department store, a Broadway, a supermarket, bakeries, liquor stores, sporting goods, hub caps, dune buggies, drug stores, water bed store um tropical fish.

E: Did you pass any places of business that you didn't like?

X: The only thing that comes to mind, and I'm not sure I didn't like it, but what came to mind was a purple nude dancing place on a corner that we passed.

E: What in particular did you see in that place?

X: What did I see? It looked like a building made of cement bricks that had just been washed in purple. And there were nude women painted all over the outside of the building, and I think it said topless.

E: She is starting to pick up my double meanings when she begins to wonder about my question of how soon she would forget me. She is right about the fact that she should not let me get in the way of her using herself.

R: She is gaining insight into her claustrophobia, her fear of heights, and the operation of her own conscious-unconscious system. Her final comment about noticing the purple nude dancing place is not elaborated, but it is hard to believe that she does not realize its possible connection with the fact that you always wear purple clothing [The senior author is partially color blind, but he can distinguish shades of purple] and the sexual connotations in your remarks. In any case it strongly suggests her unconscious is picking up the sexual associations present in your two-level communication. You are evidently still concerned about her readiness to deal with the sexual issues, so you do not use this possible opening to talk about sexual matters.

Ideosensory Induction Utilizing a Psychodynamic Complex

E: How are your hands?

X: Misty.

E: Must be you have a warm heart. How soon will you warm up your hands? [Pause]

X: They are getting warmer. [Pause]

E: Close your eyes. [Pause] Lean back in your chair. [Pause] And just keep sleeping deeper and deeper.

R: Here you deliberately associate her sweating with warm heart and, by implication, sex. Then, before she can respond or interfere in any way with this association, you immediately begin an ideosensory induction to trance by asking how soon will her hands warm up. That question is trance-inducing because to feel an adequate response of warmth, she must first go into trance. Since you have already associated warmth with heart, sex, and sweating, this choice of induction reinforces and extends these associations. Your initial association of misty and warm heart put her on an inner search for your meaning. That inner search is characteristic of the everyday trance when people pause for a moment's reflection over a puzzling question or task. You then immediately make use of this momentary inner focus to initiate a trance induction that also utilizes the inner associations (warmth) that are occupying her at that precise second. We could summarize the whole process as follows. You gave her two trance-inducing tasks simultaneously: (1) The association between symptom (misty) and warmth (sex) puts her on an inner search, and (2) the question about warming up her hands requires trance for an adequate response. These two approaches are interlocking and mutually reinforcing because they have the common theme of warmth. This common theme is itself trance-inducing because you tied it to a central psychodynamic complex (warmth, sex, sweating) that is present in her unconscious. Whenever we touch upon a person's complexes, of course, there is a spontaneous *abaisse-ment du niveau mentale* (a lowering of consciousness) that also facilitates trance. No wonder, then, that she immediately responds with the ideosensory response of warmth and enters trance.

Autonomous Trance Training

E: While you are sleeping more and more deeply, I am going to make some calls. [E dials and makes some telephone calls of a professional nature, discusses setting up future appointments with R, etc. After about five minutes he returns to X].

R: In the initial stages of trance training you sometimes give the patient a free period to learn to go deeper into trance in an autonomous manner, by whatever means they have at their disposal (Erickson, Rossi, and Rossi, 1976).

Exploratory Ideomotor Questioning

E: Breathe very deeply, X. And either nod or shake your head gently in answer to my question. Do you mind being with me? [She nods her head yes.] You do mind. Is there somebody else you want with us? [Pause, no response] All right, I will repeat my question. Are you willing to be alone with me? [Shakes head no.] Do you know why? [Pause, no response] All right, another question. Do you know why you have what you call claustrophobia? [Shakes head no] Do you know when your sweating first began? [Shakes head no] Do you know when you'll approach the harp to play? [Nods yes]

R: After five minutes of autonomous trance-deepening you judge her ready to respond to some

exploratory ideomotor signaling. You usually like to use head nodding or shaking because that utilizes well-learned and automatic movements that people frequently carry out without realizing it in everyday life. Patients, therefore, may tend to be more amnesic for head signaling that they cannot watch versus finger or hand signaling, which they can witness when their eyes are open.

E: When I begin by asking about being alone with me, I'm trying to affirm the sexual associations of the first session. I'm letting her go into her sexual dynamics.

Posthypnotic Suggestions: Consciousness Need Not Control; Undoing Repressions in Central Psychodynamics

E: Later, after you are awake, you will suddenly but not immediately give me the date and place, doing so out of context of the general conversation. Do you understand me? [Nods yes] That is, we could be talking about gourmet foods, Minnesota as a gopher state, and you will suddenly intrude upon that conversation the date and place, and after having uttered those things, you will realize that is the time and place when you will approach a harp. Now do you understand? [Nods yes]

R: Why do you use this approach to breaking through her amnesia about when her sweating began? Are you giving the unconscious the opportunity to intrude itself with the help of any chance association that may be related to the significant material?

E: In training a rifle team for the international shoot, I told them to let the sight wander back and forth, up and down, all over the target. You don't know just when you'll squeeze the trigger.

R: The conscious mind will not know just when, so the unconscious will have an opportunity to intrude and squeeze the trigger at just the right moment. You are taking pressure off the conscious mind and giving responsibility to the unconscious. Did you explain that to the riflemen?

E: I did not explain it to them. I said to them they might not even know when their finger squeezed the trigger. It takes all the pressure off because it is not necessary for them to know. The only necessary thing is for the bullet to hit the target.

R: The conscious mind need not know the precise moment. You are allowing the unconscious to play a bigger part in the response.

E: And the conscious mind can be more comfortable because it isn't pressured to do it at an exact moment. A small child always asks, Can I do it when I want to? The feeling of comfort and freedom is very important. You don't have to know the exact time.

R: You allow this freedom for the unconscious to make its own response in its own way in its own time. You depotentiate the erroneous sets of the patient's conscious mind that presumes to control everything and thereby open freedom for the individual's creative unconscious.

Structured Amnesia

E: Another question: Are you willing to be alone with me briefly? [Nods yes] That is nice. Now would you within your own mind think about the happiest event in your life. Just think about it. You don't need to tell me. Also think about the most wretched moment of your life. And you don't need to tell me. [Long pause]

R: After giving her an important posthypnotic suggestion, you return again to the question of her willingness to be with you. It continues the sexual connotation, but placed here it tends to structure an amnesia for the posthypnotic suggestion that came between the two forms of the same question.

E: Yes, all this through here has sexual connotations [happiest and most wretched moments].

R: An immediate absorption into sexual preoccupations would serve as a distraction that might also facilitate an amnesia for the preceding posthypnotic suggestion.

Serial Posthypnotic Suggestion for a Negative Hallucination Training

E: Shortly you will awaken, wondering where the others have gone. [Pause] It will rather surprise you. Why did they leave? Was there any purpose? Now slowly awaken. [Pause as she opens her eyes and reorients to her body a bit.]

R: You feel it is usually more effective to give a posthypnotic suggestion in a serial form where the posthypnotic behavior is integrated with ongoing waking behavior or typical patterns of waking behavior (Erickson and Erickson, 1941). In this case you don't directly suggest she won't see the others when she awakens. Only the very best hypnotic subjects would be capable of such a strong negative hallucination this early in their training. You give a more subtle form of suggestion that can utilize many already existing mental patterns like surprise, and questions about why they left, etc.

Trance Awakening with Amnesia by Distraction

E: What do you think is my favorite gourmet food?

X: Chicken?

E: Take a slice of bread, butter it generously with peanut butter, then cover it with a thick layer of cheese. Put it under the broiler until the cheese is melted. Butter it with peanut butter, cover it with a thick layer of cheese, put it back under the broiler until the cheese is melted.

X: Trying to remember if I ever had cheese and peanut butter.

E: Here I begin with a breathing spell about my favorite food.

R: This also serves as another distraction which tends to render the preceding trance material

amnesic.

Confusion and Unconscious Search: Depotentiating Conscious Control

X: I don't know what you are about?

E: What do you think I am about?
[Long pause]

X: I don't know right now.

E: What don't you know?

X: Well, like yesterday, I thought I knew what you were about, oh, in some ways.

E: How do you feel about containing another entity?

X: Mixed. I feel relieved in some ways and frightened in others.

E: What should you be frightened about?

X: I guess it is a lack of control. If there is another entity, then there are things over which I don't have control.

E: Why must you have control? [Pause]

X: Well, it is very frightening for me to be out of control.

E: How much is it frightened less?

X: For me to be out of control? Quite a bit, I think.

E: Now let me clarify that for you. In this room you have relinquished control to me. Out of this room you will have all your own control, and you have relinquished it in this room to enable me to help you, that's all. My first daughter-in-law was a marvelous hypnotic subject. I took her to a study group in Phoenix to demonstrate and discuss hypnosis. I intended to use her and I couldn't get a single response from her. After we got back home, she said, Will you forgive me, Dad, I had to find out if I had control. I have had that happen on several occasions. They had to find out if they had full control.

R: She tries but cannot figure out the relevance of this conversation for her therapy when she says she doesn't know what you are about. Your effort to give her a breathing spell actually confuses her and sends her on an unconscious search. That sort of inner exploration is actually the kind of mental set you try to enhance for trance work. You therefore immediately return to therapy work with your question about containing another entity. She then confirms the basic problem of many

patients: They are usually afraid to give up conscious control, they do not trust their own unconscious to find solutions and new ways of coping.

E: With the example of my daughter-in-law I give her another breathing spell. I'm also assuring her that she does have control, that's all right. But you really do have it. I want her to be absolutely confident about herself.

Paradoxical Suggestion and Distraction

E: Now what you want is more control of yourself. If you relinquish control in relationship to your hands, you have relinquished control in your relationship to what you call claustrophobia. But you can now have full control. You didn't even tell me to go to hell.

E: You give a seemingly paradoxical set of suggestions when you tell her she can have control, and yet if she relinquishes control of her hands, she relinquishes control of her claustrophobia. You mean that if she allows her unconscious to deal with her hand problem, it will also deal with the claustrophobia. But you don't state it in a clear, rational way for left hemispheric understanding, as I have here. You present it as a seeming paradox of having control yet relinquishing control. Such a paradoxical presentation will momentarily jam her critical faculties so her unconscious again will have an opportunity to interfere. Then, before she can recover her critical faculties, you are off with another provocative statement about telling you to go to hell. This now distracts her further, so your suggestion about the connection between sweating and claustrophobia cannot be dealt with consciously and must remain within, where only her unconscious can receive and work with it.

Trance Induction by Depotentiating Conscious Sets: Evaluating Posthypnotic Capacity

[X is immobile with a trancelike stare.]

E: Is there anybody else here?

X: In this room? [Long pause] I can't give you a simple answer.

E: Then give me a complex one.

X: Well there are three or four other people here, but they are not.

E: They are not what?

X: Not impinging or something.

E: Not impinging. [To R] Would you like to ask a question on that point?

R: How are your hands feeling right now?

X: Wet and warm.

E: They are warmer. Let's let them keep on being warmer and warmer.

R: The effect of your double depotentiation of her unconscious sets with paradox and immediate distraction is that she is sent on such an intense inner search that she is, for all practical purposes, in a trance. You recognize this and ask a question about the presence of others to evaluate her capacity to follow your subtle posthypnotic suggestion about wondering where the others have gone.

E: She is saying, I'm in a trance but I don't know it. Reality isn't reality. She is denning: I do not know my conscious state, I do know my trance state, my unconscious state.

R: Her answer about people not impinging or something is a bit like the trance logic when a subject sees a hallucinated person seated in a chair but also sees the chair as if the hallucination were transparent [Orne, 1962]. She is aware yet not aware; she is following your negative hallucination suggestion to a mild degree. You therefore deepen her trance involvement by requesting ideosensory behavior that can only be accomplished by the unconscious: she is to allow her hands to get warmer.

Hypnotic Enhancement of Psychodynamic Complexes

E: Where are you going to put your hot little hands? Answer. [Pause]

X: On my face?

E: That wasn't your first thought. Do you know now? You don't have to bury your thoughts, do you? Even though some are unfamiliar.

How soon would you have those hot little hands?

X: How soon would I have them?

E: Um hum.

X: Where I was thinking of putting them?

E: No, how soon when you can have hot little hands to put somewhere.

X: They are hot now.

E: It is perfectly socially acceptable to tell her to let her hands get warmer and to speak of hot little hands, but now we all know!

R: You are actually getting her sexual psychodynamics involved in this apparently innocent ideosensory exercise. This is again two-level communication to deal with issues you are not sure her conscious mind is ready to cope with.

E: When I ask how soon she would have those hot little hands, I'm asking, How soon will she get down to the sex?

R: When she responds with, Where I was thinking of putting them! she appears to be getting closer to the naked sexual question.

Undoing Repressions facilitating Inner Dialogue by Double Bind Questions

E: Quickly, without thinking, quickly without thinking, give me a date.

X: March 17.

E: Year?

X: 1958

E: Now what happened then?

X: That would be St. Patrick's Day. [Long pause] My boyfriend dyed his hair green.

E: All right. Now there are a lot of things that you are willing for me to know.

E: How many things are there about you that you don't want me to know? [Pause]

X: Quite a few.

E: Do you know the reason why? [Pause]

X: I would be embarrassed.

E: Now the important thing. What do you know about you that you don't want to know? Don't tell it. You don't want to know it. How many things are there about you that you don't want to know? [Long pause]

X: How many? [Long pause] Two.

E: All right. Do those two include something about a harp? Do those two include something about your hands? And you don't want to know, do you?

X: I don't want to know.

E: Why?

X: It would force me to look at something I don't want to look at.

E: Do you think it is awful bad?

X: Pretty bad.

E: And don't you want to know all the good and all the bad about you? It is only your knowledge of it.

X: It is too much.

E: What are you most afraid of? Don't tell me, tell yourself what you are afraid of. Have you done that?
Can you share it with me? [Long pause] Don't answer that question. Can you share it with others here?

X: Um hum.

E: Do you want to? [Pause] Is it as bad as it first started out to be?

X: No.

E: [To R] You see what I did. I protected her all along the line, and it reduced the seriousness of it.

R: Yes.

E: Have your remembered something bad?

R: This question, of course, is designed to bring up in her mind all the most intimate associations she is not yet ready to talk about. But by simply bringing them up in her own associative process, it is an increment toward eventual expression. This is another form of paradoxical or double bind approach (Erickson and Rossi, 1975). By asking a person about what they are not willing to talk about, you bring them closer to talking about it. After she has had an opportunity to turn it over in her own mind, you again ask if it is possible to talk about it. Her inner associations are by now primed for expression since they have been brought to the fore of her awareness. Since there is a long pause, however, you realize she is not yet ready to speak, so you finally tell her not to answer the question. You are always carefully watching patients and accepting where they are. You try one approach after another to facilitate their inner work, but you always accept whatever responses they make.

Desensitization by Indirect Suggestion

E: [Turning to L, who has had some training in psychology] What do you think about desensitization? [Pause]

L: Is that a question? I just heard the word.

E: Have you seen it?

L: Yes, it is a good way to do it.

R: You give her a rest here as you ask her boyfriend, L, about the process of desensitization you have just been involved with. You have been desensitizing X to her fears about revealing herself. This is also an indirect suggestion to X that lets her know she is desensitized and may be ready for more self-revelation.

Control and Fear of Self-Revelation

E: [To X] Is there anything unspoken? That you can do safely?
[Pause]

X: I'm afraid that my hands are going to be this way for the rest of my life. E: And what way is that?

X: Misty.

E: What is bad about that? [Long pause]

X: Well, it is revealing of me. And very uncomfortable. It is revealing because in other ways I seem to have so much control, and then there is this way in which I have absolutely none. It is as if at any moment this sort of sign emerges that I am not what I seem or something like that.

E: That you are not what you seem. And what exactly is that big lie? Do you know it? Have you admitted it fully to yourself?

X: I guess not.

E: Do you want to?

X: No.

R: In this section X clearly reveals her need for control and her fear of revealing herself. There is sometimes a tendency for the hypnotherapist to err in the direction of uncovering unconscious material too quickly. You carefully avoid this danger by emphasizing that patients need not tell until they are ready to do so with a feeling of comfort and safety.

Giving up Conscious Control

E: So you want to have a lack of control in that regard. And earlier today you said you wanted full control. What are you going to do about that? [Pause]

X: I want to say give it up, but it doesn't make too much sense.

R: You always have this apparently peculiar tendency to point out how patients do not want control even when they thought they did. You are again trying to release the rigid grip of their conscious mind over their unconscious.

E: I point out that contradiction. Now when does a girl want to have a lack of control?

R: During orgasm.

Automatic Writing

E: I can only remember the girl's last name when I was teaching in Michigan State University in a class of psychologists working for their Ph.D.'s. In one class a girl named Erickson, no relation to me at all, said, I have some hideous secret and I don't want to know it but I ought to know it. Can you do anything about it?

I said, yes, easily. I said take a pencil and while you are looking at me, let your hand write automatically that big troublesome secret.

Her hand wrote it and I saw her take the piece of paper and she folded it and refolded it and refolded it and she slipped it into her purse. Some months later she said, Why am I telling you this secret? I broke my engagement. I said, Well, you have broken your engagement. Why are you telling me? I bet anything there is something in your purse that will tell you. She said, You are ridiculous. I said, It is fun to be ridiculous. She very carefully emptied out her purse. She said, Where did this piece of paper come from? She unfolded it and it read, You are not going to marry Mel, you are going to marry Joe. And she did. But she was engaged to Mel. I think it was important for her to know her secret. All kinds of secrets.

E: I tell this seemingly irrelevant story about automatic writing, but it illustrates an identical psychic situation of having a hideous secret I don't want to know.

R: The incredible aspect of your telling this story as an illustration is that in her followup letter written three months after this session, she reports almost the identical situation: She gave up one boyfriend to marry another. I almost feel ESP is operating in you, but you deny that.

E: I believed she was in a sex conflict, and you can't have a conflict without two opposing objects. When I said, 'All kinds of secrets,' I made it apply to X as well.

Working Through Conscious Resistance

E: A recent patient of mine told me she was afraid to fly on a plane. And do you really know your fear? This great big lie you are telling yourself. Don't you think you ought to know all of it? When do you think you will have enough courage to know it? [Pause]

X: Later.

E: How much later? [Pause]

X: Tomorrow.

E: All right, now tell me. Jeff searching through his pockets all except for the last one. He didn't dare look in the last pocket for fear he would drop dead. Do you understand how Jeff felt? Do you really think you will drop dead if you know it? [Pause] It just seems that way. How much time do you need to reach into that other pocket?

X: I guess I can do it.

E: Just guess.

X: I can do it.

E: Do you suppose you could enjoy finding out just what that great big little fear is?

X: Maybe I could. Maybe.

R: You now tell another story which has relevance for her because X also has a fear of planes. The main purpose of this story is getting the courage to know about all one's fears. You then return to X and her fears. You don't accept tomorrow, but you don't tell her that. Instead you recount a story with the message, You won't really drop dead. That is, you remotivate her to work through her conscious resistances by telling her the humorous Mutt and Jeff story about our exaggerated fears of self-revelation.

Relocating Dental Pain

E: A forty-year-old man came to me and said that I was a good hypnotic subject in college. I have a dentalphobia. I know you suffer endless pain, excruciating pain when you go to the dentist. And I have neglected my teeth, they are in bad shape, and I have got to have dental work done, and going to a dental office means pain. Can you hypnotize me? I said Why not let the dentist who will be doing the work on you, do it? He saw two dentists I had trained, and they worked on him separately and jointly. They couldn't induce a trance. So I had them bring him to a study group. I told him for the time being to keep his fears, keep his pain, but to go into a trance. In the trance I told

him to keep his pain, all his belief in pain, and to go to the dentist and know that all his pain was in his left hand, and hold it away from him. And tell the dentist by no means to touch that left hand. The slightest breath on his left hand would be excruciatingly painful. Throughout all his dental work the pain was out there. If he ever goes to a new dentist, the new dentist will wonder why. This thing you don't want to know, has it anything to do with your hands or harp? [Pause]

R: She continues to pause, so you tell her yet another story.

E: I am giving her a breathing spell but at the same time it is giving her instruction. I told the dental patient to locate his pain in his hand. She can have all the pain of self-realization, but she could know what she really wanted in spite of the pain.

Utilizing Explosiveness to Reach the Unconscious

E: All right, now answer this question explosively. [To R] Would you say a word explosively.

R: Damn it!

E: Can you [X] say a word explosively?

X: No!

E: How do you know the meaning of that word? You know you don't want to tell the meaning of that word, do you? Answer this question explosively. Should you tell the meaning of that?

X: No!

E: Answer this, ought you?

X: Yes!

E: Are you?

X: Yes!

E: When?

X: Later!

E: How much later? [Pause]

X: In fifteen minutes.

E: All right, but you can say it explosively.

X: Fifteen minutes!

[The senior author now occupies her in small talk about her home and family for fifteen minutes. Without her realizing it, he is actually utilizing many female and sexual symbols - fish, box, things coveted, etc. - conversation that will keep her unconscious primed to the task at hand.]

E: Explosiveness is a sudden welling up of the unconscious and everyone has had that experience. Now I'm asking her to have her unconscious mind explode new understandings.

Comfortable Self-Revelation: Altering a Lifetime Identity

E: Now will the disclosure be in connection with harp, your hands, or something else?

X: With the harp and my hands.

E: Fifteen minutes has not yet gone by. How ready are you?

X: I'm ready.

E: You want to, now?

X: It is not going to seem so bad.

E: That is too bad, isn't it?

X: Should I say it?

E: Sure.

X: I never did want to be a harpist.
[Pause]

E: What do you want to do in relationship to the harp?

X: Play just for myself.

E: And whose idea was it that you be a concert harpist?

X: I always blamed my Dad, but it might have been mine. I think originally it must have been Dad's.

E: Now why did you have wet hands?

X: I know why. So I wouldn't have to play.

E: As an excuse.

R: When her self-revelation does come, it is surprisingly free of emotional trauma. Not wanting to be a concert harpist seems to be such a simple pragmatic fact, yet for her it is giving up an identity built up over a lifetime. One of her major mental frameworks about herself has been altered.

Insight Therapy to Support the Reorganization of the Symptom Complex

[A fifteen-minute conversation takes place wherein X now experiences a flood of insights about her family's psychodynamics and her symptom of sweating.]

R: Now begins a flood of insight and conviction about the source and nature of her problems in her family. You are here utilizing the classical means of insight therapy to support the reorganization of her psychic economy so that symptom formation is no longer necessary.

Ideomotor Signaling to Facilitate Further Insight

E: Now why do you think you have claustrophobia on the plane? Let your unconscious mind answer this question, and you just wait if you don't know the answer. Your unconscious mind will answer with a head movement after it has digested my question. Can you in any way say anything to indicate why you have claustrophobia on the airplane? [Long pause as X closes her eyes] Either a nod or shake of the head involuntarily. Do you know what it was? Does your unconscious mind know it? [Pause as her head nods yes very slowly] Do you consciously know it?

X: Yes.

E: What was it?

X: When my brother and I were little, we fought like cats and dogs, and one day when I came home from school I was angry with him about something and tore a page out of his stamp collection book. He hauled me into a closet and nailed it shut with a cat inside with me. I don't like cats either. It was on St. Patrick's Day.

E: There is nothing bad about knowing it, is there?

X: No, I'll beat the hell out of my brother when I go home [laughs].

E: I think it is delightful to know all the good and the bad. Comb your memory, see if there is anything more you ought to know about yourself. I was returning from somewhere in New York state by plane in a bad blizzard. [E. now tells an amusing story about an uncomfortable plane trip he once had. He is evidently tapping into her associations about airplanes to give her an opportunity to bring up her fear of flying. She

does not pick up the hint, however, so he has her review all her psychodynamic insights and the critical trauma of March 17,1958, when her brother nailed her in a closet, which Erickson believes may also account for her fear of flying.]

R: You do not rest content with that major flood of insight about her sweating. Now that she is opened to doing creative inner work, you take advantage of her availability and press on to her claustrophobia with an ideomotor approach to facilitate the flow from unconscious to conscious.

Review of Psychodynamic Insights: Resolving the Airplane Phobia

E: You really concentrated on not knowing. You have had lots of practice having sweating. Now you can have ahead of you a little practice of being dry-handed and hot-handed. Now is there any more help that you want?

X: No, right now I have a compelling need to run to the airport and catch the first plane out.

E: It is a nice feeling, isn't it? Are you going to be completely open and truthful to yourself from now on?

X: Probably not.

E: Well, we aren't perfect you know, but let's make self-concealments as small as possible and not disabling. How do you feel about it - in two days' time learning all this about yourself?

X: I guess I kind of feel as if I was on the verge of deciding about it, about knowing about it for a while. I am somewhat relieved that it is out in the open now.

E: Any anger at me for uncomfortness?

R: Here you have her review all her newly acquired insights so they can be integrated on a conscious level. You are also exploring the possibility that her fear of flying may be related somehow. As a final touch you give a lot of permissiveness regarding sexuality in the form of a two-level communication about hot hands. She then reveals an apparently spontaneous resolution of her airplane phobia when she says she feels a compelling need to run to the airport and catch the first plane out.

Gradualness of Symptom Diminution: Creative Reorganization of Psychodynamics

E: You are aware that it will take a while before you will get dry hands.

X: Um hum.

E: That isn't so embarrassing to you now, is it?

X: No.

R: You again make sure she knows that the symptom will disappear gradually over some time. You thereby give her system a fair chance to reorganize itself and forestall her fears of failure. Thus you are not involved in the simplistic notion of removing a symptom, you are doing vastly more: You are facilitating a creative reorganization of her psychodynamics so that a symptom is no longer necessary. Time is needed for that continuing process of inner adjustment.

The Utilization Theory of Hypnotic Suggestion

E: I hope you have enjoyed this and you are aware of the fact that you are a good hypnotic subject?

X: I don't want to take too much credit for myself being a good subject.

E: You can take all the credit. All I have done is say words and in so doing I have stimulated memories, ideas that you already had, and then you acted on those memories. You have memories of the time when you didn't even know your hand was your own. And you don't even know when you first knew where your ears were. And you don't know how you finally located your ears. Parents like to have a child point to the hair, forehead, eyes, nose, mouth, chin, and ears. But when did you really know where your ears were?

X: I don't know.

[Erickson demonstrates knowledge of ear location by touching the right ear by reaching with the left hand behind the head.]

E: One time you didn't know those were your hands, so you tried to pick up your right hand with your right hand. It took you a long time to learn to pick up your left hand with your right and your right hand with your left hand. So you have a whole bank full of memories and understandings, and all I do is say something that touches upon those memories. Yesterday when I said, 'Try to stand up, I tapped into your memory bank to a time when you couldn't stand up. And there was a time when you couldn't sit down because you didn't know what sit down meant.
There was even a time when you didn't know you were a people. All I needed to do was tap into your memory bank and you couldn't talk.

R: That is our theory of hypnotic phenomena.

E: Um hum. [Pause]

R: In these closing remarks you are actually giving a clear outline of our utilization theory of

hypnotic suggestion. Suggestion is *not* putting something into the subject; suggestion is the process of stimulating memories and ideas that you already had that can be acted on by the subject. Suggestion is simply the process of evoking the subjects' own internal associations and helping them utilize these associations for new purposes. All so-called hypnotic phenomena are actually dissociated bits and pieces of behavior that were once normal in earlier stages of development and the initial stages of learning.

E: Knowing things and not knowing them at the same time. [Erickson tells another of his favorite stories about his daughter Christie, who screamed and carried on for seven days until she finally stood up and took 142 consecutive steps the first time she walked. She just knew she was a people and thus had to prove it.]

Full Disclosure About Hypnotic Phenomena: Control, Freedom, and Behavioral Flexibility

E: Now you don't need to ever let anybody hypnotize you unless it is for your purposes. And nobody can control you, and you can defy me any time you want to, or anybody else. You are a free citizen, and be free with yourself. It is hell, isn't it, to be tied there to sweating and to have unpleasant feelings on the plane.

[Erickson now tells an amusing story of how he overcame a lifetime aversion to caraway by simply chewing enough of it until he began liking it. He thus proved to himself that he could change his tastes if he wanted to.] I did need to know that I could alter my behavior, and you can do the same with your sweating. Is there anything more? I have talked to you so extensively. Should I charge you?

X: No!!!

E: That is wonderful! That is really wonderful!

E: Now will you send me a Christmas card?

X: OK.

E: It has been very, very pleasing to know you.

X: It is very pleasing to know you too.

E: Have a good time in ... and I hope I see you on the way back.

R: I've frequently witnessed how at the end of a therapy process you give full disclosure to your patients about the nature of hypnosis. In particular, you emphasize that they actually have control over the process and they can use it for any constructive purpose. You dispel any lingering misconceptions about the process of control by giving control and freedom to the patient. It is ridiculous for the therapist to believe that secrets must be kept from the patient. A full

understanding of hypnotic phenomena and the methods of hypnotherapy can only help the public and individuals seeking help. With this final story of how you overcame your distaste for caraway, you send her off with a good model of self-change and behavioral flexibility.

E: Her No! in response to my question about a fee was highly explosive. . . . If she could be explosive with rne, she can be explosive with anybody.

R: Here you gave her a social opportunity to use her newly acquired self-assertiveness and at the same time, by not charging her for the sessions, you compensate her for allowing us to tape her sessions and publish them. The request for a Christmas card serves as a simple follow-up device.

A Note on the Creative Nature of Psychotherapy

[*The following is an edited version of one of the senior author's efforts to formulate an overview of a half a century of hypnotherapeutic explorations.*]

Although we have made an effort to generalize the principles involved in this case, we must acknowledge that each psychotherapeutic encounter is unique. Erickson continually comments on the theme that every hypnotherapeutic endeavor is a creative exploration. This is so because behavior, whether in the ordinary waking state or in hypnotherapeutic trance, is not necessarily logical, well-ordered, properly pertinent, or even reasonably appropriate to the situation or conditions evoking it. It may be logical, illogical, meaningless, irrelevant, random, misdirected, nonsensical, metaphorical, humorous or whatever. It is usually impossible to predict with precision just what an individual's response will be in any therapeutic encounter because the simplicities and complexities of behavior and its reasonableness and idiosyncracy derive from many permutations of unknown experiential factors in the person's lifetime of learnings. At the very most, only broad generalizations can be made. All too often, however, these generalizations break down or are lost in a maze of complexities when a particular therapist faces a particular patient at a particular time and place.

Hence, when the problems of distressed, disturbed, and abnormal behavior are encountered, any treatment approach must integrate the individuality of both the therapist and patient. There is no rigidly controlled or scientific method of eliciting the same behavior from one or more patients under the same conditions at different times. Even when the range of responses seems to be greatly limited, totally unpredictable behaviors may occur. Thus while general scientific principles of psychotherapy certainly exist (this principle of its essentially creative character being one), the utilization of these principles requires a continual appreciation of the unique and exploratory nature of all psychotherapeutic work. Psychotherapists cannot depend upon general routines or standardized procedures to be applied indiscriminately to all their patients. Psychotherapy is not the mere application of truths and principles supposedly discovered by academicians in controlled laboratory experiments. Each psychotherapeutic encounter is unique and requires fresh creative effort on the part of both therapist and patient to discover the principles and means of achieving a therapeutic outcome.

This individualized and creative approach is particularly important in hypnosis. In seven years of studying the senior author's approach, for example, the junior author has frequently requested the demonstration of a particular hypnotic phenomenon with a particular patient during an ongoing

therapy session. Much of the time the senior author rejected such requests with humorous scorn because he felt the junior author should have realized that the request was inappropriate or impossible for that particular patient at that time. Whenever he undertook the requested demonstration, however, the senior author was usually successful in evoking most of the hypnotic phenomenon associated with clinical work such as ideomotor action, catalepsy, dissociations, amnesia, hyperamnesia, time distortion, the alteration of cognition, emotions, and, of course, the modification and transformation of symptomatic behavior that we see in this case.

The most common reason the senior author gave for both his successes and failures was the degree to which he was able to evoke and utilize the particular patient's motivation and repertory of experiential learning. The most remarkable hypnotic effects could be evoked because of the nature of the transference relationship and the importance of these hypnotic responses for the patient's much desired therapeutic outcome. The failures, particularly those involving the hypnotic effects that the senior author was most experienced in evoking in experimental settings, were likewise accounted for by their apparent irrelevance to the patient's real needs. Although the senior author used some standard routines in setting up hypnotic experiences, he was perpetually tuning into and utilizing the patient's own mental frameworks and idiosyncratic association patterns.

A Three Year Followup

On the next three Christmas holidays, X sent the senior author a Christmas card with a bit of family news and some pictures of her newborn children. Each message confirmed her freedom from symptoms, her new life orientation with her growing family, and her pleasurable cultivation of music for herself.

Case 6 Demonstrating Psychosomatic Asthma with Shock to Facilitate Symptom Resolution and Insight

A basic hypnotherapeutic approach to psychosomatic symptoms is to demonstrate clearly and unequivocably how they are controlled and maintained by psychological processes. Such a demonstration breaks through limiting preconceptions about the organic nature of the problem and usually puts the patient in touch with the psychodynamics of the problem. If it is correct that psychosomatic symptoms are more closely associated with right hemispheric functioning (Galin, 1974), an hypnotic demonstration of the psychogenic control of the problem may be making contact with the actual hemispheric sources of the symptom, since trance itself is considered to be a right hemispheric activity (Bakan, 1969; Hilgard and Hilgard, 1975). This helps us understand why it is that spontaneous insight into the sources and psychodynamics of the problem frequently follows closely upon a demonstration of the psychological control of the symptom. The trance experience opens up common pathways between the psychodynamics and the sources of control of the symptom. The following case, written by the senior author, is a typical example of how this approach can be used.

Psychosomatic Asthma

Mrs. G., aged thirty-five, married ten years, with one child aged nine, sought a psychiatric consultation. This was in protest to the repeated diagnosis she had received from a half-dozen different allergists to the effect that her chronic asthma, lasting from November through April, of ten years duration, was largely psychological. The pertinent history obtained was that the excitement of her wedding had been followed within two days by the long-expected death of her bedridden mother. The mother had left no will but, as a wedding present for her daughter, had extracted from the father a solemn sworn promise that, when she died, he would dispose of the farm, give the daughter half of the proceeds, and then, if he wished, he could retire on his half.

After the funeral the father told her that his promise to the mother was meaningless and that she would receive only half the yearly income until he died, when she would inherit everything. She and her husband angrily took their departure to live in another section of the country. Within two months the couple became reconciled to the father's actions and initiated a friendly correspondence in late October. The father replied, and his first letter found her in bed with a severe cold. Her recovery was slow, and this was attributed to a pulmonary reaction to atmospheric impurities resulting from the mining industry in that town. Asthma developed as a complication, but with the advent of warm weather this vanished. In June they moved to the San Fernando Valley, but in November, presumably because of the smog, she again developed asthma, which persisted until May. In June they moved to San Francisco, but the following November the asthma reappeared and persisted until May. Further moves were unavailing. Wherever they went, the asthma redeveloped in November and ended in May.

Inquiry about the father disclosed that he had continued farming but in a peculiar part-time fashion. He planted the crops, cultivated them, and harvested them. This done, he turned the entire management over to an employee and spent the winter in a somewhat distant city in ease and comfort. With the advent of spring, he returned to the farm and worked hard until the last harvest was completed. Immediate inquiry about the frequency of her father's letters disclosed that in the summer he was always too busy to write and that he reserved his weekly letter-writing for the leisure of his winter life. The patient failed to recognize any possible connection between her asthma and her father's weekly letters.

She was asked if she were willing to have the writer prove definitely that her asthma was either psychogenic or organic. She emphatically replied that, in either case, she would be tremendously relieved, but added that it was unquestionably organic since it had begun with a cold, had been aggravated by the atmospheric impurities of the mining town, and only occurred during cold weather. Furthermore it always disappeared with the advent of warm weather. Also, it had to be organic, since in ten years she had never had a single attack in the summer, and she was the same person psychologically in both cold and warm weather. She was told that hypnosis would be useful as a diagnostic aid, and she consented readily to be hypnotized.

She proved to be an excellent subject, developing a deep trance easily. She was given rapid training in posthypnotic suggestions. She was then instructed during trance that at a specified cue (when the writer tapped his pencil three times) she would be given a memory task, a most important memory task, which would be defined at the proper time. She agreed to follow all instruction and, also, to go to sleep whenever another specific cue was given (when his cigarette lighter was dropped into his ashtray). She was awakened with a comprehensive amnesia for the

trance experience. After a few casual remarks, further inquiry was made about the possibility of summer attacks of asthma. She was most positive in her denials.

Mention was made that the clock indicated the time as 2:17 P.M., and she was reminded that it was a very hot July 8th in Phoenix, Arizona. Then she was asked if she thought she could develop a severe attack of asthma exactly at 2:37 P.M. She declared the idea to be most ridiculous. She was assured that if her asthma were psychogenic, it was both possible and probable. However, if it were organic, she need have no fears. Somewhat puzzled, she waited for further elaboration, but the writer merely directed her attention silently to the clock.

At 2:25 P.M. she was asked if she felt comfortable. She replied that she was merely puzzled, because watching a clock certainly could do nothing to her. At 2:34 the comment was offered that only three minutes remained before she would or would not develop an asthmatic attack. She only smiled in reply. At 2:37 she turned expectantly to the writer. Immediately the writer tapped his pencil on the table three times (this was a cue for the posthypnotic suggestion to remember) and said, Remember fully, completely, just as if you were reading it, the content of any letter your father has written to you. A violent asthmatic attack ensued.

During it she was told, The day is hot. It's the 8th of July. It is summertime. There are no fumes or dust or cold. You have not a recent lung infection. You are having a severe asthmatic attack. It began at 2:37, twenty minutes after I said it would, *if it were psychogenic.* It will stop when I say so. It *is* psychogenic! Shall I remove it at 2:45 or 2:47, because I can. Do you see this cigarette lighter? That's all it is. It is neither medicine nor magic. But when I do a certain thing with it, your asthma will disappear. Watch it carefully. Be sure you know, really know, that your asthma is psychogenic. Now watch. Immediately the lighter was dropped into an ashtray. A deep trance state ensued, and she was told to sleep deeply, comfortably, and to awaken free of her asthma and with a full recollection of everything. This she was then to relate to the writer.

She responded fully, and upon awakening she began to verbalize freely and comprehendingly. Her recollections may be summarized as follows: Her mother had long been bedridden because of paralysis, cardiac disease, and accompanying respiratory distress. Her father had never treated her mother or her very kindly, and he was tremendously guilt-ridden. Shortly before her first attack of asthma, she had received a letter from a friend, hinting strongly about her father's undue interest in a woman known to be promiscuous. Her asthmatic attack followed her father's first letter. Thereafter she dreaded from week to week his next letter, but felt duty-bound to answer each letter. His return to the farm each spring gave her a sense of relief because she knew he would be too busy to engage in undesirable activities or to write to her.

When she had completed her summation, she was asked what she intended to do. Her reply was that she would think matters over thoroughly and decide on a course of action. Subsequent reports disclosed that she had visited her father, discussed the situation with him, engaged a lawyer, and intimidated her father into executing legal instruments ensuring her control over and eventual ownership of her share of the farm, and giving him his freedom to do as he wished with his share. Since then the father has handled her property well, but he has been slowly dissipating his share.

He still writes regularly each winter, but the patient has had no further asthmatic attacks since the one induced in the office on July 8, 1949. She was last seen casually in late June 1954.

It will be informative to closely examine the stages of how this case progressed. The five stages of our general approach outlined earlier will be numbered and emphasized in italics, together with the senior author's use of shock and surprise to facilitate a reorganization of her understanding.

There is an initial period during which the patient consults a number of physicians for the organic treatment of the problem. Since this repeatedly fails or results in only short-term placebo effects, the patient is reluctantly told that it must be psychological.

The patient arrives at the psychotherapist's office with much inner confusion and tension, still protesting that it cannot be psychological. In spite of these protests *confusion*is an indication that *the patient's original frame of reference of the organic nature of the problem has been shaken and depotentiated at least in part.* Confusion is a sign of being lost between having to give up the organic framework and not yet really understanding the new psychological framework. Confusion is thus an important psychological prerequisite for therapeutic change; it signals patient-readiness for change even though they do not always recognize it.

The therapist in his initial survey of the problem ascertains for himself the relevant facts and possible psychodynamics of the symptom. In this case the senior author rapidly found the possible psychogenic sources from the obvious motive for a problem: (a) the patient's clouded inheritance under the particularly trying circumstances of her marriage and almost simultaneous death of her mother; (b) The regular association between the patient's symptoms and her father's letters. When the patient failed to recognize any possible connection between her asthma and her father's letters, the senior author recognized a possible block or dissociation that could be a factor in the formation of the psychosomatic symptom. At this point, when all the facts are clarified, some patients do recognize the connection. They gain insights and work them through with the therapist's help to a final resolution of the problem. No hypnotherapeutic intervention is necessary.

Although this patient could not grasp the psychological associations outlined by the facts and circumstances of her life, this initial inquiry did establish *(I) rapport and a therapeutic frame of reference* on a conscious level. It now remained for unconscious dynamics and experiential sources of recognition and knowing to be activated.

The senior author approaches these unrecognized sources of the symptom with a hypnotic demonstration of the psychological control of the asthma. He first trains her to experience trance effects and to follow posthypnotic suggestions. As is typical of his general approach to symptom problems he *(2) demonstrates with her own experience how her unconscious can control her behavior and thereby indicates that the locus of therapeutic change will be within her unconscious.*

During trance she is given careful suggestions to respond with an important memory when given a specific cue. She is not told what the memory is to be about, since that might only arouse further conscious resistance. Her unconscious, however, will probably respond to the obvious implication that it will have something to do with her asthma by activating its relevant unconscious search

programs in that area. Implication is a most effective means of *(3) evoking searches and processes on an unconscious level* that can be precipitated into consciousness when given a specific cue.

Before preceeding the senior author added a safety measure. After giving her training in following posthypnotic suggestions, he instructs her to go to sleep - that is, to enter trance - whenever a specific cue is given. Thus any behavior or symptomatic processes that threaten to get out of hand could be immediately attenuated by having her enter trance.

He then gives her unconscious time, from 2:17 P.M. to 2:37, to align itself to produce an asthmatic attack on cue if the asthma is in fact psychogenic. The unconscious does not work by magic. Time is required for it to do its own work. The senior author judged it would take at least twenty minutes to work through the inhibiting limitations of the patient's conscious sets, which declared the idea to be most ridiculous. An expectation was given for an asthmatic attack at 2:37.

The senior author then allows expectancy and tension to build for twenty minutes. At the appointed time, 2:37, she turns (1) *expectantly* to him; her readiness is apparent. He then gives the expected posthypnotic cue (tapping his pencil three times) and gives her the critical memory task of recalling the content of any letter your father has written to you. A violent psychogenic asthmatic attack ensues. She is thus precipitated into a *(2) state of shock during which her habitual mental frameworks and patterns of defense are momentarily depotentiated.*

During this critical period the senior author simply states all the obvious facts regarding the psychogenic nature of her asthma. When one's habitual mental frameworks (the generalized reality orientation) are so shaken by (3) *shock and surprise,* one tends to grasp onto any suggestions or belief system that will reestablish security and comfort. The facts about the psychogenic nature of her asthma are then reinforced through the security and comfort that follow from the posthypnotic cue (lighter-ashtray) to enter a deep and comfortable trance state from which she can awaken *free from her asthma* with a full recognition of everything. The senior author thereby *(4) demonstrates her release from symptomatic behavior* while opening the possibility of (5) *her gaining insight into the sources and psychodynamics of her problem.* She gains these insights and makes her own plans about how to settle her problems.

Case 7 Symptom Resolution with Catharsis Facilitating Personality Maturation: An Authoritarian Approach

This case illustrates how hypnosis can be used effectively even when the patient is a difficult and unresponsive hypnotic subject with whom only a light trance state is possible. Three two-hour sessions were required to achieve even that light trance, but it was enough to present the basic suggestion: Your unconscious will know what to do and how to do it. You will absolutely yield to that need and give full expression to me. When finally that has been done completely, you can then recover from your present problem. Although the senior author could not evoke any of the classical hypnotic phenomena with this patient, the above suggestion was enough to *assign the locus of therapeutic change to his unconscious.* The patient's unconscious was given time to

incubate until the next session, when his *usual conscious frameworks were suddenly depotentiated with the shockingly authoritarian demand* to, Shut up with your conscious mind and its foolish requests for medicine, and let your unconscious mind attend to its task!

That was enough to precipitate an unusually violent and prolonged catharsis that proved to be the vehicle for the resolution of the patient's psychosomatic symptom and a striking change and maturation of the total personality. The periods of the patient's intense catharsis could be looked upon as altered states in which personality reorganization could take place. But scientific conceptions cannot do justice to this happening; it is essentially a love story. It is presented as written by the senior author more than a generation ago.

None of Your Lip!

Pietro, in his mid-twenties, had been forced to give up his position in a symphony orchestra because of an inexplicable swollen lower lip. This had developed suddenly after an altercation with the orchestra conductor. The swelling was so severe that his lip was a full two inches thick. During the three years that this swelling had persisted, he had been treated by more than one hundred doctors, and the measures employed ranged from physiotherapy, hot compresses, medication, and bed rest to infrared and X-ray therapy. No benefit was derived.

He was finally sent to a general psychiatrist, who promptly referred him to the writer for hypnotherapy. The salient points in his history are as follows: He was born in Italy, but his family emigrated to the United States when he was four years old. His father, a hard-working baker by trade, had an overwhelming ambition for his son. Since the boy had shown very early a keen interest in music, the father had determined to make a famous musician of him. Accordingly, the boy's training started at the age of three on the piano, while the father explored the field of musical instruments to determine the proper choice of an instrument. He finally selected the flute.

To understand the training the boy received, a brief statement concerning the father is necessary. He was a domineering patriarch, who ruled the family in an incredibly rigid fashion. He ate first, the choicest portions, and his wife and children stood silently at hand, ready to obey his slightest wish. Since he owned his own bakery, he worked on the average of twelve hours daily, seven days a week. Home conversation was essentially a series of reports on the daily activities of each member of the family. His wife reported on her housework, shopping, and the activities of the preschool children. After the children entered school, they reported on their daily work, and during vacation, on their day's activities. He listened intently, discussed their reports authoritatively, was lavish in his praise and encouragement for good accomplishments, and equally lavish in his condemnation of foolishness. Since his education was limited, when the older children entered school, they had to sit in judgment upon each other concerning those matters for which the father felt that he lacked knowledge. As for himself, he too gave a daily report in which he discussed his own accomplishments and his own shortcomings. The father was never wrong in anything unless, unaided, he himself reached that conclusion independently. He had early learned the expression None of your lip and its variations, and it had become a standard daily cliche. Nobody ever game him any lip, a constant boast that characterized every report that was given of the family's daily activities and relationships. He treated his employees in a comparable fashion but

was so eminently fair that he had their loyalty.

All home activities were conducted by rule and on a time basis, which he would alter magnanimously as he saw fit. Thus shoes were polished in so many minutes per shoe, and the lawn was mowed in an exact length of time at a set hour. The advent of a rain disrupting this schedule was met by him with a dissertation on the need for meeting reality by adjustment to whatever situation arose through schedule alteration and no sacrifice of obligations. Thus, the time gained by a rain that rendered unnecessary the watering of the flower bed had to be utilized in special tasks reserved for such contingencies. Play was regarded as an essential part of living, but its duration and character were predetermined. Thus, the boys played ball and the girls played with dolls for regular periods. All was orderly, constructive, and systematic.

Since Pietro was to become a famous musician, a special set of rules was established for him. Calisthenics rather than play, biographies of musicians rather than fairy tales, etc. became his lot. Schoolwork had to be average, since there had to be a conservation of energy for his daily after-school music practice. The other children were required to have excellent grades. Next to the father, Pietro received the more choice portions at the table. At first the father supervised the son's musical training, and he was a highly intelligent man with an excellent ear for music. So many hours a day were spent playing the piano, not to play music but to establish nimbleness of the fingers, dexterity, and absolute precision of movement. Then a teacher was engaged to teach him to play compositions so that he would learn music. Since the father was profoundly appreciative of music and would discuss it happily and enthusiastically, he succeeded in inspiring his son with equal enthusiasm and love. The first lessons with the flute were supervised by the father, and their character is best summarized by the father's explanation, You musta feela da flute before you playa da flute.

Taking the flute, an expensive instrument, out of its case and putting it back, lifting it to the mouth, lowering it and again raising it, measuring its length and diameter by finger movements, learning to balance it with utter accuracy and learning the exact distance from his lip to place it, constituted those initial lessons, practiced endlessly until the father was satisfied. Always the father's praise was lavish and his patience unlimited, thereby rendering his otherwise unbearable demands endurable. Then the learning of one note at a time, one key at a time, and the increase and decrease of volume followed in the same rigorous fashion. Along with all this the piano practice continued, so many hours at the piano, so many hours on the flute, so much time for calisthenics, so much time for rest, so much time in discussion to learna da soula da music. This latter, of course, was the salvation of the patient, and when he was in therapy, it was a thrilling, inspiring experience to have him discuss the soul of music. Then an excellent teacher was engaged, who stipulated the length and frequency and types of lessons, while the father restricted himself to the stipulation of the amount of intervening practice and other essential activities.

After graduating from high school, Pietro spent twelve hours a day for two years perfecting himself as a flutist. Then he was allowed by his father to seek an audition at the age of twenty. His first application resulted in his engagement by a well-known symphony orchestra as first flutist. His father's ambition was satisfied except for certain refinements. His son's position in the musical world had been achieved, but there remained certain additional achievements of a personal nature. His son must now fall in love, marry, and father children, so that he would learna da feela, da

sweetness, da love da woman, da beauty, da laugha da bambino.

The son, as always, acquiesced, and a procession of girls was paraded through the home, but unfortunately, at a concert he met the girl of his choice. His father was in deep despair. The girl was Yugoslavian and not Italian. The son was adamant but did yield somewhat by agreeing to postpone marriage. Partially consoling to the father was the fact that the girl came from an artistic family, was a college student, a trained singer, could paint excellently, and had a brother who was a sculptor of note in Yugoslavia.

For over two years he played in the symphony orchestra. Then a new conductor was engaged, who promptly became at sword's points with most of the orchestra members because of his harshly critical, dictatorial manner. At a practice session he accused the patient of an error, and when the patient attempted to protest, he told the patient that no lip was wanted out of him. At the next rehearsal the patient's lower lip was slightly swollen and his playing was faulty. When he attempted to explain, the conductor harshly told him again, I don't want any more lip out of you or you can resign. His resentment toward this was tremendous, and he dared not express it in any way. Neither did he dare to tell his father. Within a month his lip was so swollen that he was forced to resign, and he explained the situation to his father solely on the basis of his lip condition.

Then began the frantic search for medical help, while in addition, he practiced playing the piano and fingering the flute never less than nine hours daily. During these three years the father watched the swollen lip with increasing anxiety and impatience and finally expressed his feelings with long, bitter denunciations of the medical profession and demands that his son seek a more competent physician. At last he lapsed into bitter, frustrated silence on the subject. The romance with the Yugoslavian girl was terminated. She left the state to complete her college studies and to take additional training in singing and painting.

Clinical Course

The first few interviews were devoted to the securing of the above history. He did not like this and suddenly demanded that history-taking be dispensed with and hypnosis employed without delay.

At the fifth interview an effort was made to hypnotize him, but he proved to be a difficult, unresponsive subject. However, after three sessions of two or more hours' duration, a light trance was induced. This was utilized to suggest, as emphatically and as authoritatively as possible, that his swollen lip was of psychological origin, that it could be cured, that it was an external manifestation of a profound and compelling need for his unconscious mind to manifest and to express behavior which had been repressed, ignored, overlooked, and consciously forbidden over the years. He was told that his unconscious must express itself completely, however terrifying or irrational such expression might seem. Furthermore, his unconscious would know what to do and how to do it, and he would absolutely yield to that *need and give full expression to the writer*. When that had been done completely, he could then recover from his present problem. These posthypnotic suggestions were given with much emphasis and repetition and in the most authoritative, dictatorial manner possible. At the close of the session he was curtly told to ask no

questions, to go home, to let his unconscious mind prepare for its task, and then, at the next appointment, he was to appear promptly at the exact hour and to let his unconscious begin its task without delay or any conscious interference. This extremely authoritarian approach was deemed appropriate because it utilized the patient's previous life experience and current expectation that effective guidance always came in an authoritarian form. The senior author was simply utilizing his authoritarian expectation.

At the next interview he entered the office as instructed but immediately asked for some medicine for his lip. He was told emphatically, Shut up with your conscious mind and its foolish requests for medicine, and let your unconscious mind attend to its task! His reaction was one of intense, violent anger. He leapt out of his chair and loudly and bitterly denounced the writer as a wretched example of an incompetent, lowly profession, sparing neither profanity nor obscenity to express his opinion. The entire hour was spent in this vituperative attack. Exactly at the close of the hour he was told sternly, Your unconscious can now shut up, and at the next hour it will continue, exactly on time, and do a more thorough and better job. Leave the office at once.

He appeared exactly on time for the next appointment and launched into another diatribe, even as he closed the door behind him. The interview was terminated in the same manner as the previous one, and this pattern was followed essentially throughout the course of therapy. For nine months, two hours each week, this procedure was followed, except that about once a month he would arbitrarily be told that the next immediate appointment would be different, but no further information would be given. However, as he entered the office on such occasions, he would be greeted with the demand that he give a good discussion of such separate topics as the meaningfulness of music, how the members of an orchestra feel and sense during and after a concert, how the individual expresses his emotions and his life experiences, hopes and fears, in his own playing. The patient entered into these sessions with the same intensity and enthusiasm manifested in the hostile behavior, and he was truly inspiring in his discussions.

At first the denunciations were primarily of the writer as a member of the medical profession and then as a medical man in a specific field. This led to a denunciation of the writer as a member of the human race, particularly as a descendant of the Norsemen, who ravaged and pillaged every land to which they could sail their ships. He seasoned these vituperative comments with many choice Italian phrases, which he kindly translated for the writer. This developed then into a vituperative description and vilification, both collectively and individually, of all of the writer's progenitors, with the exception of the writer's parents and grandparents, back to the beginning of time. Should his discussion be broken off in the midst of a sentence at the close of the hour, the next hour would be marked by a completion of that sentence and a continuation of the topic. Also, his trips home on the bus were usually devoted to a study of what better insults he could offer at the next interview. From the writer's progenitors he turned to the topic of the writer as a man, first as a physiological creature. When this was exhausted, he turned to the topic of the writer as a member of society in general but with an inheritance only of pillage and rapine. Having treated this topic exhaustively, he progressed to the writer as a family man. As he developed this topic, there occurred a marked change in his motor behavior. Previously he had paced the floor agitatedly and gesticulated violently. Upon developing this topic, he added to his motor behavior by leaping at the writer to shake his fist underneath the writer's nose, and explained how he would like to strike and hurt the writer and to inflict all manner of mayhem upon the writer's body. At

each demonstration he demanded the writer's close attention while he pantomimed how he would like to gouge out the writer's right eye, his left eye, etc. Additionally, he gave emphasis to his utterances by expelling flatus, belching and spitting.

As he developed the topic of the writer as a family man, he took up, item by item, the various things he had told about in describing his father's home. Thus the writer's table behavior, his attitude toward each of his children, his demands regarding home activities and work, and other habits and characteristics were speculated upon extensively, unfavorably, and with intense bitterness and hatred. Hour after hour was spent on this general topic with an increasing outpouring of hatreds and resentments and extravagant declarations. Finally one day, near the end of the hour, he made the first mention of his father in any of his tirades by declaring, If you were my father ... Immediately he paused in a frightened fashion, sat down weakly, and gasped, But you aren't my father, you aren't my father, you aren't my father. In a friendly tone of voice, he was told, No, I'm not your father. Your unconscious has been talking to me, saying things that would help you to understand your feelings toward your father. Now that you have said all the things that have piled up in you for years and years, your lip can get well. You have given me all the lip you did not ever dare to give anyone, and which you kept to yourself. You are free, your lip will now heal. The only thing you need to do is to look at your father and see him as one man looking at another. You are grown up now. Tell your father simply what you want and feel and wish, limiting yourself only to those things he can understand. Things he can't understand do not need to be said. His reply was, I'll have to think. I'll talk to him tonight.

His report at the next interview was that that evening, at the usual gathering for the day's report, he had told his father in effect that he was a man, that he knew what was right and good, that thenceforth he would be answerable only to himself, and that he was now ceasing to take parental orders. To this he added that his lip would be healed shortly. His father's response was typical. After a long, thoughtful silence the father arose, walked over to the patient, shook hands with him, and in Italian said simply, My son, I'm an old man. I forgot that you are grown up. Please forgive me.

Within a month the patient's lip was normal. While he practiced daily, there were no longer nine-hour stints. He announced his intention to his father of going east to some large city, and he chose the one where his former fiancee was studying. He secured employment as a waiter until an opportunity arose a few months later for an audition. He was engaged as a flutist in a large symphony orchestra. He renewed his engagement and sent his fiancee on a visit to his parents and the writer. She was a most charming girl but most unhappy about the growing unrest in Europe. She told of her plans to return to Yugoslavia to see her family. She was not seen again until 1947. The outbreak of World War II had trapped her in her native land. She had joined a guerilla force and fought the Nazis under most difficult conditions throughout most of the war. Then she had been captured and put in a forced-labor battalion and brutally treated. Finally she had escaped and managed to get back to the United States. She was no longer a charming girl. She was an aged, stooped, gray-haired woman, scarred badly on the face, arms, and legs. She inquired about Pietro, but could only be told that, although he had written repeated enthusiastic letters to the writer, the entrance of the United States into the war had ended the correspondence. Also, his father had given up the bakery and had gone into war industry, and thus all contact had been lost. She accepted this information resignedly and bade the writer farewell.

Case 8 Sexual Dysfunction: Somnambulistic Training in a Rapid Hypnotherapeutic Approach

A retired professional man who greatly respected the senior author's reputation telephoned for an interview to deal with a personal problem. In the first part of this single, one-hour interview the senior author illustrates his typical approach in facilitating somnambulistic behavior. He establishes a therapeutic frame of reference and then deftly utilizes many of the indirect forms of suggestion and a series of posthypnotic suggestions to initiate the close rapport and following behavior that is characteristic of somnambulism. He illustrates how two-level communication and a continual discharging and displacement of resistance are of primary importance.

In the second part of this session he illustrates how a classical hand levitation approach to trance induction can be used as a rich context for introducing many therapeutic suggestions in a symbolic as well as a direct form. Therapeutic suggestions are introduced during those first moments of initiating trance experience when patients' attention and expectancy are frequently at their highest pitch. In this unusually rapid approach the patients receive therapeutic suggestions before they realize what is happening. Their consciousness can be so fixated on the novel experience of hand levitation that they do not notice the therapeutic suggestions. The therapeutic suggestions are, therefore, received by the unconscious in a way that bypass some of the patients' conscious, habitual attitudes and learned limitations.

If we translate the terms conscious and unconscious into dominant and nondominant hemispheres, we may have the neuropsychological basis for describing a new hypnotherapeutic approach. Occupying the dominant hemisphere with a trance induction such as hand levitation which can be easily lateralized can release the nondominant hemisphere to receive therapeutic suggestions phrased in the symbolic language of the nondominant hemisphere. Part Two of this session is a demonstration of this approach which utilizes hemispheric interaction in trance induction and suggestion in an unusually clear form.

Part One: Facilitating Somnambulistic Behavior

E: Tell me what your problem is.

P. I lost my wife a few years ago. She had been ill for a couple of years. We always had a normal sex life. But after she died, I seemed to be absolutely impotent and I couldn't get an erection. That did not bother me because I did not plan to remarry. Now I've met a woman I want very much. I want to marry her. I did all the pushing. She thought we should wait longer. I could have lived with her, but I didn't want to. I want to marry her. But I found in the love-making process with her that I didn't get the sexual feelings that I knew I had. I realize I'm older and those things don't happen so frequently. I'm sixty-eight. Since I called you a few days ago, this has changed. I haven't had intercourse, but I've had erections during the love-making. I just want to feel secure in this. We are planning to marry in about five weeks. I want to feel secure for her as well as for myself.

E: Have you an interest in archeology?

P: No, not very much.

E: You know that seeds found with Egyptian mummies have sprouted after 5,000 years.

P: Yes, I know that.

E: Now is there any reason for you to think that your penis located in a vagina won't become tumescent?

P: No, not now there isn't. It's changed in the last few days, but that was my worry when I called you.

E: Why should you ever worry about your heart function or your pancreas function, your salivary glands?

P: Well, I never worry about those things, but this was a personal relationship. That was the thing that worried me. I wanted to be sure. And I think she wanted to be sure, too.

E: All right, from the physiological point of view you really shouldn't have a worry.

P: I don't think so.

E: You don't think so?

P: No, I should say I'm sure.

E: From the psychological or emotional point of view you can have a worry.

P: Yes.

E: Do you think from an emotional and psychological point of view that you can have any doubt when she is nude?

P: No, I don't think so now, but three or four days ago I did.

E: You never forget the problem at hand, but you translate it into many other avenues of the patient's experience. You utilize their other experiential learnings to deal with their current problem.

R: That's what you do right in the beginning of this interview. He states his problem and you immediately ask about his interest in archeology. This enables you to bring up the idea of seeds sprouting after 5,000 years which, of course, it a humorous but meaningful analogy with his problem. You're immediately using another modality of his knowledge to establish that it is possible to regain a life function that has been unused for some time. This is your first approach to

facilitating a therapeutic frame of reference. You then ask *a question* about the functioning of the heart, pancreas, and salivary glands which leads to the *implication*that he does not have to worry about penis erection because that's also an automatic function. You're thereby introducing another therapeutic frame of reference: Unconscious processes within the body will regulate penis erections just as they do other functions once he gives up the limiting and inhibiting effects of his conscious worry about it. The patient objects by saying a personal relationship is involved. You then utilize this to confirm that from the physiological point of view you really shouldn't have a worry. This resolves the physiological aspect of the problem and enables you to define the problems as psychological or emotional in a manner that he can easily accept. Then with your hypothetical question about any doubt when she is nude you help him acknowledge that even this psychological aspect of the problem is resolvable. Thus in the first few minutes of the interview you have facilitated series of acknowledgments from the patient that structure a very strong *therapeutic frame of reference* for the hypnotic work that will follow. In his last remark the patient is already placing the problem into the past. He approaches trance with a very high *expectation* that his now very limited problem can be resolved with ease.

Trance Induction: The Early Learning Set

E: Now sit with your hands on your thighs like this. And just look at one spot there. And just look at it continuously.
You do not need to talk.
You do not need to move.
You actually do not need to move.
Just look at that one spot.
And many years ago
you went to kindergarten,
first grade.
And you were confronted
with what seemed then
an insurmountable task
of learning the letters of the alphabet
in all their many forms.
And it seemed an insurmountable task.
But you did form mental images
for every letter of the alphabet.
And you formed mental images
of the numbers.
And you formed those mental images
to remain with you for the rest of your life.

R: Here you induce trance without any initial introductory remarks because this professional man already knows its therapeutic possibilities and he has a positive expectation about it. This early learning set induction (Erickson, Rossi, and Rossi, 1976) tends to facilitate age regression by *indirect ideodynamic focusing* that evokes early learning experiences. This activation of early learning experiences is a foundation for the hypnotic phenomena you will later evoke.

Ratifying Trance: Body Language in Trance

While I have been talking to you
your respiration has changed,
your pulse has changed.
Close your eyes N ... O ... W.

[Pause as the patient's eyes close and his head bows down very slowly, bit by bit, until it almost touches his chest]

You go deeply into a trance
and enjoy the feeling of comfort
and satisfaction *all over.*

[Pause as patient's body tips forward a bit precariously]

You can lean back in the chair.

[Pause as patient's body reorients back comfortably in the chair]

R: You begin your process of vocal conditioning with your slow drawn-out N . . . O . . . W and then emphasize that in a deep trance one can enjoy feeling comfort and satisfaction all over. This is a form of indirect suggestion because we know that such comfort is a characteristic of trance.

E: My emphasis on satisfaction *all over* includes his scalp, nose, buttocks, and penis.

R: The patient does not recognize this as an *indirect suggestion by generalization:*Since his penis is the problem his unconscious will tend to automatically focus some of that suggested satisfaction there.

E: The fact that his body tips forward may be an indication that he is leaning toward the light of love; he had been leaning away from it after his wife died.

R: Leaning forward may be an indication of a positive rapport. Does that mean that a leaning backward or pulling in a direction away from the therapist is an indication of a negative transference reaction or a problem between therapist and patient?

E: It can indicate a difficulty with the ideas being presented.

Posthypnotic Suggestions Initiating Somnambulistic Training: Being in Trance Without Knowing It

And now I want you
to realize something.
Shortly after you awaken

I'm going to say something to you.

R: This posthypnotic suggestion is a way of initiating somnambulistic training. It is a very easy suggestion to accept because after a patient awakens he naturally expects you will say something. He doesn't realize, however, that when you do say something, you're actually giving a posthypnotic cue that will initiate another trance. Your earlier research (Erickson and Erickson, 1941) indicated that subjects reenter trance when receiving posthypnotic cues and carrying out posthypnotic suggestions. When you begin to say something after trance, they will tend to reenter trance even though their eyes may be open and they may act as if they are awake. This is your definition of the somnambulistic state: A person acting as if he is awake but capable of following the therapist's hypnotic suggestions.

E: Yes, with hypnotic training you want them to be content with the thought that they are awake.

R: Even though they are really not. Do you define that as the somnambulistic state? The patient thinks he is awake, but he is following you so closely and is thereby capable of carrying out so many hypnotic responses that we say he's actually in an altered state called trance. He is not critical and initiating his own behavioral directions; he is waiting for your suggestions. He is in trance without being aware of it.

E: I once told a subject to act as if he was awake with all of us who were in the room. But when a totally unexpected person came in the room, the subject could not respond to his presence. He never heard the newcomer speaking to him.

R: Indicating that there was a special rapport with those already present in the room that excluded any strangers. Such an intense state of rapport is characteristic of somnambulistic trance. I'm beginning to believe that patients are frequently in somnambulistic trance without the hypnotherapist recognizing it or knowing how to use it.

E: I certainly agree! Most have such fixed and rigid ideas of what somnambulistic behavior is. [The senior author goes on to point out how subtle changes in behavior that indicate the presence of therapeutic trance are frequently missed by many therapists. See Erickson, Rossi Rossi, 1976.]

Utilizing Patients' Motivation to Reinforce Suggestions

And you can be surprised
that you ever really have doubted
yourself.

[Pause]

R: You throw in a therapeutic suggestion here?

E: To reinforce the preceding posthypnotic suggestion.

R: You utilize the patients' own motivation for therapy to reinforce your suggestions.

E: All your suggestions in therapy should be a connected whole.

Hypnotic Amnesia Facilitating Somnambulistic State

Now it isn't necessary for you to remember
what I say to you in the trance state.
But your unconscious mind
will remember.
But all of us know very little
about what the unconscious mind knows.

R: This is a permissive suggestion for amnesia. You don't command amnesia-that might only arouse conscious resistance. You are apparently letting the patient do something easy: It isn't necessary for you to remember. This implies that it's too hard to remember (as we all well know from many experiences in everyday life.)

E: If you tell anyone they *have to* do something, they invariably come back with they *don't.*

R: You then admit Your unconscious mind will remember. But all of us know very little about what the unconscious mind knows. This tends to reinforce amnesia and the role of the unconscious while *depotentiating the importance of his more limited conscious mental sets.* This emphasis on conscious amnesia and the significance of unconscious functioning is another way of facilitating the somnambulistic state.

Deepening Trance by Rehearsal

I'm going to arouse you
and put you back into trance.

E: Awakening and putting a patient back into trance repeatedly is a way of deepening trance (Erickson, 1952).

R: Is it also a way of further depotentiating his conscious orientation, a sort of confusion approach to somnambulistic training?

E: Yes, you're training the patient to respond in a therapeutic way.

R: You're training him to respond to you.

E: And you base your therapeutic suggestions on his own patterns of behaving.

R: By deep trance you mean that the patient is following you very closely in accord with his needs.

Questions as Direct Suggestion in a Permissive Manner

And you are going to do everything I ask you to do.
Can you be surprised
at your ability
to make true whatever I say?

[Pause]

R: Your first sentence here seems to be a shocking authoritarian demand for obedience.

E: Everything I a*sk* you to do. I did not say, Do what I tell you to do.

R: When you ask, you are actually making a permissive request that the patient could refuse. Then you follow it up with a very innocuous-sounding but strongly reinforcing *question* about being *surprised* at your ability to make true whatever I say?

E: Even infants like surprises.

R: A surprise also implies that the unconscious will be active and surprise the conscious mind.

E: Too many therapists tell their patients to do this or that rather than ask. That's an iron hand covered with a lot of velvet.

Discharging and Displacing Resistance: Use of the Negative

And you will make true whatever I say,
will you not?

E: You will, will you not? If anybody is going to use the negative, it had better be me.

R: If the patient has a resistance in the form of a no within, then your use of will you *not?* tends to displace and discharge the no. Beginning students in hypnosis are usually trained to express suggestions in a positive manner. That is a valid approach. You assume, however, that resistance in the form of contrary trends is always present. You therefore use negatives in this rather curiously concrete way to pick up the patient's negative and convert it into a constructive direction. This does not make sense from a rational, left-hemispheric point of view, but it may be effective because trance is a right-hemisphere phenomenon, where such concrete transformations are easily possible.

Hypnotic Poetry Bypassing Conscious Resistance

In spite of any thinking you do,
what I say will be true.

R: This poetic couplet is another way of dealing with resistance. Many patients fear that if they have contrary thoughts during trance, the therapeutic suggestions cannot be effective. Your couplet reassures them on this point. The smooth pattern of sound and stress in this couplet suggests it may be an example of Snyder's Hypnotic Poetry (1930), which bypasses the critical, intellectualistic left-hemisphere so it can be accepted by the right.

E: I'm bonding my therapeutic suggestion to whatever resistance he may have within.

R: In this case you don't necessarily eliminate resistance but rather add your therapeutic suggestions to it. It's a way of utilizing the patients' resistance so that whenever they express it to themselves, they find themselves also expressing the therapeutic suggestion. This is especially important for this type of patient, who seems so cooperative in his manifest behavior. Since he is so cooperative on the outside, his resistances must be hidden within. You therefore utilize this inner resistance by adding a constructive suggestion to it without even having to bring it up with the patient.

Apparent Trance Awakening and Spontaneous Reinduction: Individual Characteristics of Somnambulism

Take your time
and mentally, silently,
count backward from twenty to one.
Awakening one-twentieth of the way at each count.
And begin the count now.

[Pause as P appears to awaken in about one minute]

Pretty hard to awaken wasn't it?

P: Um-hum.

[E answers the phone, and as he does so P closes his eyes and evidently goes back into trance.]

E: And it's hard to awaken,
but you can awaken again.

[Pause as P opens his eyes slowly. He does not reorient much to his body, however, so we may presume he is still in trance.]

And awaken with a very comfortable feeling.

P: I feel comfortable.

E: Why did you go back into trance the second time?

[Pause as P looks perplexed]

Your unconscious mind understands a lot more than you do.

R: It's an indication of his intense somnambulistic rapport with you that he closes his eyes and goes back into trance when you remove your attention from him by answering the phone. He is now following your earlier posthypnotic suggestions that he would go back into trance after awakening. If he were really awake, he might have moved about a bit or related to me since I was right next to him. But he completely ignores me and all the recording equipment. Deep trance does not mean a patient is stuporous or unconscious; it does mean that a patient's attention is intensely focused on what is relevant, so that everything else is ignored. You ask him to awaken again, but he only opens his eyes. When you tell him to awaken with a very comfortable feeling, he responds in an *almost exact* paraphrase, I am comfortable. This exact following of your words is another indication of the somnambulistic state. Why is he perplexed when you ask him why he went into trance the second time?

E: There is a *retardation of intellectual processes* that easily leads to perplexity in the somnambulistic state.

R: So here we have three characteristics of somnambulism: (1) the intense rapport; (2) the exact following of the therapist's remarks that are in accord with the patient's own needs; and (3) the lack of mental initiative. The somnambulistic state does not mean the patient is an automaton but that he is extraordinarily well related to the therapist.

E: It's his conscious mind that is perplexed. I verify that by adding that his unconscious understands a lot more than he does. I keep out of the situation; don't say, I know what's going on. I say, *Your* unconscious knows.

R: Are there any general characteristics of somnambulism, or do we have to pick them out as highly individualized manifestations in each person?

E: You have to pick them out for each individual; they will vary depending upon the purposes of the patient.

R: This patient showed little initiative in his somnambulistic state, but other persons might show a lot - expressing their fantasies, etc. Is there a general difference between an active and passive somnambulism?

E: This patient did not like what he was receiving from himself, therefore he remained passive in order to get what he could from me. That's why I worked for amnesia and perplexity to depotentiate his conscious sets.

R: Those were ways of depotentiating his habitual conscious attitudes so that an unconscious search and process could be initiated to facilitate a therapeutic response. Thus, even when the patient is in a very passive and receptive state, you do not resort to directly programming him with what he is to do. Rather you make an effort to help him sidestep his own conscious

limitations so his unconscious potentials can become manifest.

E: The patient had better believe in his own unconscious.

Hypnotic Phenomena as Early Patterns of Behavior: Implication Evoking Early Psychomotor Patterns? Two-Level Communication for Therapeutic Suggestion via Metaphor

E: And all of your life
since the age of one
you have known you could stand up.
Right?

P: Um-hum.

E: And now you know you can't.
Try it. *You can't.* [Said very quickly and softly]

[Pause as the patient makes a few slight abortive movements with the upper part of his body and looks about, a bit distressed]

E: Since the age of one you have known you could stand up implies that before the age of one you could not. At the same time this is a two-level communication dealing with his problem in a metaphorical way: Not being able to stand up is like not being able to get an erection.

R: You choose a hypnotic phenomenon that has an unconscious connection with his psychological problem, so that when you later resolve the hypnotic phenomenon (allow him to stand up) you may also be resolving his sexual impotence to some degree. This is an unusually clear example of indirect therapy being done on an unconscious level. This also appears to be an unusually clear example of your utilization approach to hypnotic phenomena. Do you believe that you are actually evoking an early psychomotor level of not being able to walk and then utilizing it as the basis of this hypnotic phenomenon? Hypnosis is not just imagination; it is based on the activation of the relevant neurological circuits-very often those from infancy and early childhood.

E: Yes. Those infantile and early childhood patterns have a long history

R: Because of their long history they have a certain prepotency within us; they have never been really extinguished, and when properly activated they can be expressed in behavior. It is usually more effective to activate such early psychomotor patterns by indirect means such as implication, because a direct command could evoke the doubting attitudes of consciousness that in turn block the hypnotic response.

E: You deal with the patient as a total historical being. You can rely on those neurological tracks and memories of long duration much more than you can on the very recent ones.

R: It would be well for the hypnotherapist to study early childhood development to gain a more adequate understanding of the type of phenomena he can evoke as well as hints about how they may be evoked. Most if not all hypnotic phenomena are actually early patterns of functioning. This is a distinctive aspect of your work: you believe you are evoking real mental mechanisms and unconscious processes in hypnotic phenomena. It is the utilization of an individual's early experiential learning rather than hypersuggestibility or imagination per se that is the basis of hypnotic phenomena.

E: Patients can only respond out of their own life experiences.

The Creative Process of Therapeutic Analogy

E: And now you *truly* know
how an idea can take possession of you.

[P closes his eyes and appears to lapse deeper into trance]

E: In mentioning that he now truly knows how an idea can take possession of one, you are by analogy referring, of course, to his problem: Just as an idea can prevent him from standing up, so can an idea prevent his penis from standing up.

R: He probably closed his eyes again because of a sudden realization of standing up having those different meanings?

E: Closing his eyes probably corresponded to the *inner search and unconscious processes* that actually create that meaning. To grasp such an analogy requires a creative effort on his part. Because it is his own creative effort, he is less likely to reject it than if it was simply thrust upon him as a direct statement.

Two-Level Communication: Further Somnambulistic Training

E: And rouse again
and feel very comfortable all over.

[Pause as P opens his eyes again]

How do you feel about not being able to stand up?

P: Well, it didn't bother me. I didn't want to stand up.

E: And now you can't remain seated.

[P looks around and stands up, seemingly a bit embarrassed for a moment or two]

Now you can sit down

[P sits] .

E: When he said he didn't want to stand up, that implied he had a choice. On an unconscious level it also means he has choice about his penis not standing up.

R: I see - he may want to make that choice at times. He may be using two-level communication here without quite realizing it. The further suggestion that he can't remain seated in this context now has the symbolic meaning of not being able to keep his penis down and may account for his apparent embarrassment at this point. It is also a means of further training in somnambulistic behavior wherein he follows your hypnotic suggestions even while acting as if he's awake.

E: To say that he can't remain seated is therapeutic on an unconscious level. Notice that I carefully avoided saying You have to stand up. I wanted to avoid the stand up issue because he had such difficulty with his penis standing up that it could have defeated the hypnotic suggestion on an unconscious level.

Part Two: A Rapid Hypnotherapeutic Approach Utilizing Therapeutic Symbolism with Hand Levitation: Hemispheric Interaction in Trance Induction and Suggestion

E: I want you to enjoy this experience.
One or the other or both of your hands will lift up toward your face. And nomatter how hard you try to press down, it's going to lift up toward your face.

[Fingers of the patient's right hand lift tentatively, and then the whole hand lifts with a gentle, bobbing motion]

And you can't stop it.

[Pause as P's right hand slowly approaches his face]

And there is nothing you can do to stop it.

[Pause as the hand bobs up toward P's hairline]

A little bit higher.
There is nothing you can do to stop your hand from feeling hair.

[P's hand approaches and finally touches the hair on his head]

The feeling of hair,
and you can't stop your hand from doing that.
And now you know
that whenever you wish

your penis can stand up and feel hair.

[Pause]

R: You now undertake a classical hand levitation, but your words have another level of meaning where hand levitation becomes equivalent to penis levitation. Several times you mention You can't stop it. Are you thereby attempting to symbolically depotentiate his conscious mind's ability to stop a penis erection?

E: Yes.

R: It is fascinating to hypothesize that his left hemisphere may be so preoccupied with levitating his right hand that it leaves his right hemisphere more available to accept and act upon your therapeutic suggestions given in the symbolic language of the right hemisphere. Recent research (Smith, Chu, and Ed-monston, 1977; Diamond and Beaumont, 1974; Kinsbourne and Smith, 1974) indicates that preoccupying the dominant cerebral hemisphere with one activity does tend to leave the other hemisphere free to deal with other data. This may be the neuropsychological basis of your common practice of interspersing therapeutic suggestions in the symbolic language of the unconscious (or non-dominant hemisphere) along with hand levitation or any other approach to induction that occupies the attention of the dominant cerebral hemisphere. A great deal of systematic research is now required to test this hypothesis of hemispheric interaction in trance induction and suggestion in order to ascertain the parameters under which this therapeutic approach could be maximized.

Posthypnotic Suggestion Contingent on Inevitabilities

E: And you can enjoy it.
It won't be your hair.
It won't be your hair.
It will be the feeling of hers.
And you can't lower your hand
until you've enjoyed
sensing the feeling of hair
sensing a warm body.

[Pause]

And nothing can tell you
that your penis won't stand up.
Nothing can tell you that.

[Pause]

And nothing can prevent it from feeling hair and a vagina for as long as you want.

[Pause]

And I want you to notice
your hand doesn't feel as if it's touching your hair,
it feels as if it's touching
that lady's hair.

[Pause]

E: I initiated the process of lifting toward his face and hair. Once that was well under way and could not be stopped, then I could shift it to the issue of vagina and pubic hair.

R: Having accepted the initial condition, he is carried on by its momentum to accepting the therapeutic suggestion.

E: Now he can't avoid sensing a warm body when he is with her; that's inevitable and I've symbolically tied an erect penis to her warm body when I say You can't lower your hand until you've enjoyed. . . warm body.

R: This is a basic principle of posthypnotic suggestion wherein you always make a suggested behavior contingent on an inevitability.

Further Posthypnotic Suggestion

And I want you to have the surprise of your life
because sometime today
or tomorrow
your hand will touch the hair on her head,
and you'll find
what your penis will insist on doing.
And you're going to let that be a surprise
are you not?

[P nods his head yes]

[Pause]

And you're going to be so delighted
with the forcefulness of your desire.
But you will not offend the lady.
But you will be pleased
with the very forcefulness of the desire.

[Pause]

And philosophers
of old have said,
As a man thinketh, he is.
And you'll never forget that, will you?
And now think this question over well,
are you willing to tell us something about the lady?

[P nods head yes]

E: Sometime today or tomorrow actually means anytime. It could be next month and still fall within the generalized time range of this suggestion.

R: Here you again make a posthypnotic suggestion about penis erection contingent on another inevitability (touching her hair).

E: How do you offend the lady? By either being too forceful or not forceful enough. I've covered both possibilities there forcefulness of vour desire. When I then ask him if he wants to tell us something about the lady, it implies he has choice, and if he tells us something he also has the right to hold back other things. The right to hold things back gives him potency and power.

Preparation for Awakening

All right, take your time and awaken
and just spontaneously tell us something about her.

[Pause as P opens his eyes and focuses as if he is awake. His hand remains at his head, however, and he does not reorient any other part of his body]

P: Well, she is beautiful.
She is the same age as I am.
And I never loved anyone like this before in my life.

E: I've just given him the implied posthypnotic suggestion to hold back and he responds with the generalization Well, she is beautiful. He is actually holding back. He's following a posthypnotic suggestion without even realizing it.

R: In having him hold back you're returning him to his normally awake ego controls and are thereby preparing him for a full awakening.

E: Yes, when he admits loving her more than anyone else in his life, he is volunteering that on a more conscious awake level.

Symbolically Displacing and Discharging a Lack of Confidence

E: What did you just learn about yourself?

P: More confidence, for one thing.

E: There is something lacking in your confidence?

P: Yes, there was doubt.

E: There is something now lacking in your confidence. I'll tell you what it is.
You can't put your hand down.

P: Hum!?

E: When he talks about confidence here, he' s implying a lack of confidence, so I displace it onto the hand. Put the lack of confidence in a harmless place.

R: This is a way of displacing and discharging a lack of confidence in a symbolic manner.

Two-level Communication with True Trance Awakening

E: And you can't push it down until you have a feeling of intense satisfaction.

[Long pause as P closes his eyes. He finally opens them again, puts his hand down, and adjusts his whole body slightly, as is characteristic of patients awakening from trance.]

P: Yeah, I feel pretty good now!

E: And what are you going to need?

P: Uh?

E: You don't have to tell us.

P: No.

E: But you think it over.
She's got two beautiful twins,
and both deserve a name.

[Pause]

P: Yeah.

E: After a pleasant sexual intercourse what happens?

R: You relax and your penis goes down. So your suggestion that he can't put his hand down until he has a feeling of intense satisfaction is another bit of two-level communication that he receives

just as he is waking up. This tends to build a bridge between the therapeutic suggestion on the unconscious and conscious levels.

E: He then responds with, Yeah, I feel pretty good now! A two-level response without his quite realizing it. I now continue with remarks about her two beautiful twins, which he recognizes as a reference to her breasts. If he is to make love to her, he had better appreciate her breasts.

Indirect Ideodynamic Focusing

E: Someone who liked mountain climbing was asked on a social occasion, Do you intend to do any mountain climbing this weekend? And he said, Oh, yes, but he didn't name the mountain. That was a secret between him and his wife. And every couple should have a language of love.

[Pause]

P: I feel better now.

E: And another friend of mine
was asked at the dinner table,
Would you like to have a cup of soup?
He answered, Yes, I always like a cupful.
What he really meant was, Yes, I always like a cup full of life.

P: Yeah.

R: You're here emphasizing the two-level communication about love play in everyday life.

E: Yes, these two-level communications are like the secret language of childhood.

R: Since they come from childhood, they are rich in the sort of ideodynamic responses he will need in his new love life. You are thus activating these processes by talking about them. This is another example of indirect ideodynamic focusing for a therapeutic response.

Therapeutic Restructuring of a Former Symptom

E: Now, I always tell young men,
Sometime in your lifetime you're going to lose your erection.
And what you don't know
is that your unconscious mind
is telling you that the beauty of your wife's body is overwhelming.
And to enjoy that fact.
Because that's the greatest possible compliment you both can receive.
If on some occasion unexpectedly you lose your erection,
it's a very profound compliment,

**because as soon as you realize you
have complimented her in the most ultimate fashion,
then your erection comes back.**

[Pause]

R: Do you actually believe that a loss of erection could really be a compliment, or is this just a rationalization you're offering him?

E: He's placed a bad interpretation on a loss of erection. Why should he keep that forever and ever? Life is much better if sometimes it rains and sometimes it doesn't. I've seen many cases where it really was a compliment.

Further Therapeutic Analogies

E: How long did you practice in X city?

P: Since Y. I retired a few years ago. [A general conversation now takes place about P's medical practice and his use of hypnosis on his patients.]

E: How many Ginkgo trees are there in X?

P: I don't know.

E: I was given a drive through X and passed an intersection and I said to my friend who was driving,' 'Didn't we just pass a Ginkgo tree up that side street? I've never seen one, but I'm sure it was a Ginkgo tree. He said, You're right. Later he showed me some petrified Ginkgo wood.

P: Oh!

E: [To R] Do you know the Ginkgo tree?

R: Oh yes, very well! They have live motile sperm!

P: Yes.

E: One time when I was in X, I ordered oysters. The waiter said, You're lucky, we have just two orders left. I said, I'll take them both.

[A round of laughter at the implied association between eating oysters and sexual potency. The conversation then drifts to seafood in general and P's hobbies, one of which has to do with working with fine grains and textures of wood.]

What more would you like to say to me?

P: I don't think there is anything. I just feel entirely different. I feel as if a load has been lifted off my shoulders. I just feel that I have confidence in myself that I did not have before.

E: Now I'm not able to travel, but will you send me a wedding invitation? P: Yes, I'll do that. It's a wonderful feeling. It's a good feeling. E: How do you like this?

[The senior author shows P a fine sculpture of a bird emerging from a branch of wood. The front part of the bird is carved very simply and elegantly, while the latter part of its body is not sculptured at all; it simply merges into the natural form of the wood.]

P: I've never seen anything like it.

E: Like a butterfly emerging from a cocoon. Only this time it's a bird.

P: Did you carve it?

E: No, I used to carve. Do you like wood-carving?

P: I've never done any, but I like it.

E: Would you like to see the world's largest private collection of iron wood carvings?

[The therapy session thus ends with P being shown the senior authors collection of ironwood carvings made by the Indians of Central Mexico.]

R: You terminate the interview with these further therapeutic analogies that now shift the relationship from doctor-patient to friends as you invite him into your home to look at your collection of carvings.

E: He knows I like oysters and he likes wood carvings and so do I. We share likings.

R: Since you like sexuality, then he must like it, too. This aspect of your work is essentially a transference cure as well as a way of resolving the transference, since you become just another human being with your personal tastes, etc.

Case 9 Anorexia Nervosa Paradox and Double Bind

[*The senior author originally wrote this case; the junior author has added commentaries for its current publication.*]

E: In all cases I have known of anorexia nervosa in children (about fifty, and all girls from ages nine to fifteen) there has always been a peculiar emotional relationship between the parents and the patient. It is one of concealed, repressed anger, resentment, and extreme frustration together with anxiety, concern, and fear on the part of the parents. For the patient the emotional behavior is most difficult to describe. There appears to be an underlying state of fear of all emotional involvement manifested by a submissive passivity, total lack of self-concern, the rejection of food to the point of death by starvation, a concealed fear of the parents, particularly of the mother, and

repression of hunger feelings and all autocritical faculties. Underlying all of this is a vaguely conceptualized religiosity suggestive of a poorly formed and often not verbalized identification with a messiah or a messianic purpose.

The problem of anorexia nervosa, to the best of my knowledge and experience, is emotional in character with resulting physical symptomatology. An approach I used effectively in a short period (February 11 to March 13) is as follows. I saw the fourteen-year-old patient with her mother during the first two interviews. As is typical of many mothers of anorexia nervosa patients, she answered all questions put to the daughter in a protective fashion. Having secured a thorough demonstration of the mother's interest, I told the mother politely but emphatically, Shut up and let your daughter answer the questions. I then proceeded to get general information from the girl. Then I told her most emphatically that her parents sent her to me to have me tell her to eat, but I had no intention of doing so; eating was her own problem, and she could do as she pleased.

R: In this initial approach you immediately establish rapport with the patient by telling her mother to shut up. You then facilitate the developing of a yes set by adapting yourself to the patient's own frame of reference, as you tell her you have no intention of telling her to eat. You then place the *locus of therapeutic control* within the patient by saying that eating was her own problem and she could do as she pleased. You apparently allow the patient to keep her resistances and you see to it that she has no need to defend herself against you. There is a paradox in all this and a subtle double bind. *The paradox* is that you are apparently on her side and doing the opposite of what you're supposed to be doing - making her eat. The *subtle double bind* is that by the very approach of not trying to control her behavior, you are actually establishing a rapport and relationship that will eventually bind her to therapeutic work you will soon suggest. The paradox and double bind together undoubtedly have the effect of *depotentiating some of the conscious frames of reference* so that she is now more available for whatever you suggest.

Distracting Conscious Frames of Reference

E: I then pointed out that as a medical man I could give proper and competent advice about oral hygiene. I explained to the girl that regardless of whether one eats or does not eat, using the toothbrush on the teeth and on the gums is important, and that in a proper method of oral hygiene you use a toothpaste with fluoride with the understanding that there should never be swallowing of any of the paste. After the child agreed to this, I pointed out that there was further oral hygiene which, as a medical man, I was entitled to prescribe. This was the use of a mouthwash to be used before brushing the teeth to loosen the detritus on the teeth, and the brushing of the teeth should be followed by a second application of mouthwash with absolute instructions that there should be no swallowing of any of the mouthwash. I exacted a promise from the child that my instructions about oral hygiene would be followed.

R: You now further detract her conscious frames of references by this indirect approach of focusing attention on what is actually an irrelevant problem - oral hygiene. You utilize her character structure of passive obedience to get her to follow some rather absurd and practically impossible suggestions.

Depotentiating a Messianic Complex

E: In patients with anorexia nervosa, the messianic complex and their own religious demands compel them to keep the promises made. I prescribed as a mouthwash cod liver oil, emphasizing that not a single drop be swallowed. The child rebelled by whimpering at night and keeping the mother awake. After this happened a few times, I delivered a dispassionate sermon on the wrongness of offenses against others. I described it as bad behavior requiring punishment, and since the bad behavior was not against me, but against the mother - the mother being the offended person - she had the right to prescribe the punishment. The child agreed and privately I told the mother that nocturnal whimpering is not desirable, and might be punished in any way that she chose so long as it was reasonable. The mother decided that scrambled eggs could be used as punishment. That removed food from the area of nonacceptability of the self-imposed ritual of rejection of food. Also, her body received nourishment, which, coupled with the taste of the cod liver oil, created a disruptive situation for her self-imposed passive self-destruction. Her passivity compelled her to accept food as punishment, and her messianic complex also required her to do so. Additionally, the bad taste of the cod liver oil aroused strong emotions of revulsion with consequent temptation to avoid using it, something her messianic complex and passivity precluded. Her only recourse was to rationalize or to forget something that would give her both satisfaction and guilt, all of which were destructive of her passivity and messianic complex.

She was queried just once about having secured the cod liver oil and her use of it. The mother had been instructed to oversee only the first occasion of its use, and I asked about it only once. The mother was instructed to remind the girl only once, and that was on the first overnight sightseeing trip in Arizona, to be sure to pack her cod liver oil, that it should not be forgotten for the trip.

Near the end of the treatment private inquiry of the mother disclosed that she had reluctantly purchased, in the company of her daughter, only a small bottle of cod liver oil (under 16 ounces), that she had become nauseated watching her daughter's first use of it, and that after the first two days the content level of the bottle changed very little; sometime later the bottle disappeared.

R: You accomplished a number of fascinating psychodynamic alterations at this point. Your practically impossible demand of using cod liver oil was accepted by her because her passive, messianic complex required that she accept unpleasant suggestions to assuage her guilt. Yet, since she could not follow the cod liver oil suggestion, the egosyntonic aspects of the messianic complex are shattered (Rossi, 1973b). She can only follow the cod liver oil suggestions minimally, and then apparently she engages in an outright deceit by making the bottle of cod liver oil disappear. In doing this she has to give up her messianic all good and obedient" identification and begin to mobilize her own will to survive through different patterns of behavior. The impossible task thus shattered her messianic complex (depotentiated that frame of reference) and initiated her into an unconscious search for new and potentially therapeutic responses. The other marvelous twist in all this is that you manage to keep the mother as the dispenser of punishment - you still remain the patient's sympathetic supporter. She has been disobedient and requires punishment. Food, which was formerly a reward, is now changed into a punishment that she has to accept. This is all so difficult to follow that I almost get vertigo even trying to untangle the psychodynamics in an objective fashion. I can imagine how confused and helpless the patient's

conscious mind must have felt trying to sort it all out. Obviously it could not, so she was simply open to follow your suggestions.

Depotentiating Conscious Sets and Unconscious Search

E: Then to meet the child's emotional needs further, I proceeded to talk to her, telling interesting things, boring things, exciting things, mildly offensive things, ridiculous things, highly intriguing things. I bombarded the child with a great wealth of opportunities to react to on an emotional level. As one doctor who sat in on one such interview remarked after it was over, You ran that poor girl up and down the whole gamut of emotions, and so far as she could see, you were just talking about things of interest to you.

R: You are engaged in one of your typical approaches *of fixing her attention* with your talk of interesting and intriguing things. You thereby also further *depotentiate her own frames of reference and provide her via indirect associative focusing* with many opportunities *for unconscious searches and processes* to stir her emotional life. Hopefully, this will enable her to realign her inner psychodynamics so that she can come up with a new, more adequate frame of reference for a better self-identity and more fulfilling behavior. You don't know what this more adequate frame and pattern of response will be at this point. You are simply shaking up her psychodynamics with the expectation that her unconscious will find its own way.

A Therapeutic Double Bind

E: Now the mother of this particular anorexia nervosa patient liked to travel, and I had her see as much of Arizona as possible so that in the period of February 11 to March 13 I saw the child for only a total of twenty hours. During the first two weeks she gained three pounds, lost one, and gained one back. She had lost five pounds in the month that she had been in the hospital, and her weight when she arrived was sixty-one pounds. Otherwise she was a well-built fourteen-year-old girl. After she had gained the three pounds, the mother, who simply could not understand my handling of the child, was told to stand up and to tell me her height, her weight and age, and the number of her children. She told me she was past forty, mother of five children and an M.D., that she was married to an M.D., and that her height was five feet six inches and her weight was 118 Ibs., even as it had been when she had married her husband nineteen years previously. I put on a fairly good semblance of shock at her underweight state. (Actually her height appeared to be around five feet eight or nine inches, but I did not dispute this statement.) I pointed out quite emphatically that a mother of five at that height and that age should weigh 130 pounds; and did she not consider her behavior shameful in bringing her daughter to me in a state of malnutrition when she herself was undernourished? I told the patient, I want you to see to it that your mother gains weight, and I want you to tell me of any failure by your mother to eat adequately.

R: Since the mother may have been about to interfere with her daughter's therapy, you begin to involve the mother with what may have been an indirect induction of therapeutic trance. By asking her to stand up and answer a series of standard medical questions you were actually *focusing her attention* very fixedly on herself. She was naturally in a state of wonderment, confusion, and perhaps a bit of shock about this rather unusual treatment at this stage of the game

by a fellow physician. Her *habitual mental sets* were therefore *depotentiated,*and your series of *questions* evoked a set of many problems of *unconscious search.* Your questions were all easily answered, so you thereby very indirectly evoked a *yes set.* She could easily answer your questions even if she was mystified about why you were asking them. She is thus in a mood of heightened and positive *expectancy* about what is to come next. Your denouement is swift in the form of a *double bind* operating simultaneously on mother and daughter.

The double bind is operative in the daughter as follows: 1) certainly she would like to control her mother for a change; 2) yet as she controls her mother by seeing to it that she eats adequately, the daughter is thereby setting into motion a similar pattern *of adequate eating* in herself on an unconscious level by a process *of indirect ideodynamic* focusing; wanting mother to eat adequately sets up an involuntary process of *eating adequately* that cannot help but become activated within the daughter.

The mother may also experience something of a double bind in this situation: 1) she wants her daughter to get well but 2) the daughter can only get well if the mother gives up her pathological overcontrol of the daughter. Since the mother's *habitual attitudes are depotentiated,* at this moment she tends to yield to your apparently paradoxical suggestion because she simply doesn't know how to cope otherwise. But you are not content with only this, so you add more to *overload the situation* further.

Emotional Catharsis

E: The next important procedure was to insult the girl thoroughly by accusing her of being a liar and a coward, and asserting my ability to prove it. Naturally the girl protested my accusations, whereupon I told her, Hit me on the arm. She was obviously angry, and she tapped my arm lightly. I took her to task for giving my arm a light tap and implying it to be a blow. I told her that she was a coward if she didn't hit me and that she was a liar when she tried to make me believe that a gentle tap was really a blow. The girl did indeed become angry and actually did hit me, though lightly, on the arm, but immediately turned and rushed into the waiting room and shortly returned, dry-faced and dry-eyed, and took her seat. I accused her again of being a coward and a liar, my proof being that she ran away from the consequences of striking me and went into the waiting room because she did not want me to see the tears in her eyes, and that she was a liar by returning dry-eyed and with a tearless face since I saw her tears as she left the room. Thereupon I continued to run her up and down the gamut of emotions, and I did tell her interesting, pleasing, and intriguing things also.

R: You are again attacking her messianic complex with your accusations and proofs that evoke emotional turmoil and conflicts that make evident the contradictions contained in the all-too-pious and passive view she has of herself. You have certainly focused her attention and depotentiated the false persona she has tried to maintain. It is acceptable to her because it's actually interspersed within the positive context of interesting, pleasing and intriguing things which keeps her open with a yes set and permits an emotional catharsis.

Reversals Depotentiating the Symptom Complex

E: On one occasion the mother failed to eat all of her hamburger and had wrapped part of it in a napkin, explaining to her daughter that she was going to make it a midnight snack. The patient did not report her mother's misbehavior until two days later. I took the mother to task for setting a bad example for her daughter and told the mother that she had offended against me in not obeying my medical orders. I told the girl she had offended me by shirking her duty to report her mother's behavior, and therefore, since I was the one offended, I would punish both of them, and I would choose the way I would punish them. I then instructed the mother to bring bread and cheese to my house (which adjoins the office), and she would put a layer of cheese on top of two slices of bread, place them under the broiler, and melt the cheese. She was to withdraw the bread, turn the slices over, cover the other side with cheese, and replace them under the broiler. Then each would eat a cheese sandwich under my watchful eye.

R: Now both mother and daughter are on the hot seat. Both are guilty and therefore open to your surprising punishment of making them eat. Since food is a punishment rather than a reward, they can now eat to assuage their mutual guilt. Since it's such an odd and funny sort of cheese treat, they can also accept it with good humor. They were both caught in not obeying medical orders and are now partners in crime. This brings mother and daughter together with a common enemy, which they now transfer onto you. Mother and daughter are no longer struggling against each other; therefore the basic psycho-dynamics underlying the symptom of anorexia nervosa are depotentiated.

Therapeutic Binds and Paradox

E: I then took up with my patient the fact that I didn't mind seeing her now and then, but that I really thought she would much prefer to return to her home 2,000 miles from Arizona. I also told her that I might want her to weigh 85 pounds when she returned home, but that she might want to weigh only 75 pounds. I also stated that I thought the mother should weigh 130 pounds, but that the mother might want to weigh 125.1 then explained about the daily weight variance of a pound and a half, and that while they could choose their departure weights, they better be sure those weights were at least a pound and a half more than the chosen weight. I also stipulated to the girl that after she went home, she had to gain five pounds in the first month. I then turned to the mother and said, If she does not gain five additional pounds in the first month she is home, you will bring her back to me in Phoenix where I will further supervise her.

R: You now place them in a number of simple binds that allow them to choose their own weight but always in a therapeutic direction. You then unashamedly use a paradoxical bit of negative reinforcement in your threat of having the daughter brought back if she did not gain an additional five pounds the first month at home.

Shock and Utilizing an Ethical Value System

E: The mother had kept in constant telephone communication with her husband, and he too came to Arizona with the other four children, two of whom were older than my patient. After meeting him, in a separate interview I demanded to know what age and weight he was, and he stated that he was probably five pounds underweight as a preventive measure against diabetes mellitus. I

asked him if there were any family history of diabetes and he said, No, it is simply a preventive measure. Then in an impersonal, denunciative fashion I read the riot act to the father for gambling his daughter's life by setting an example of being underweight. I told him he could not leave Arizona until he gained five pounds, advising him to make allowance for weight variance.

I then had a separate interview with the seventeen-year-old brother and sixteen-year-old sister. I asked them how long they had been aware that their sister had not been eating enough and what they had done about it. They explained that the loss of weight had been noticeable for nearly a year. They had always offered her food, candy, and fruit, but their sister had always refused it, saying, Keep it for yourself. I don't deserve it. I then read the riot act to the brother and sister for depriving my patient of her constitutional rights, the right to receive presents from her siblings. They were so taken aback by my impersonal riot act that they had no opportunity to recognize its specious character. After dismissing them, I called my patient in for a brief interview and read a most emphatic riot act to her about depriving her siblings and her parents of their constitutional rights to give her presents of any kind they wished.

R: The father, brother, and sister are all taken aback by your impersonal riot acts, which so shocked them that their habitual mental sets were depotentiated and they had to search for new and more adequate responses, which you supply with your direct suggestion about constitutional rights. You are actually *utilizing their highly ethical value system* in a way that shocks them and initiates a therapeutic change in their behavior. If they did not all have a tightly organized and rigid value system, your riot act would simply not work.

Conscience as a Metalevel

E: The mother and my patient attended my daughter's wedding, and my patient helped herself to a piece of wedding cake, although I made sure that she did not think that I knew about it.

On the day of departure the mother weighed 126½ and my patient, 76½ pounds. Before they left, my patient asked if I would permit her brother to take a picture of her sitting on my lap in my wheelchair. I agreed to this, and the brother took two Polaroid pictures. Shortly after her return home she had her father enlarge one of those pictures into a poster for her bedroom. I then reiterated to my patient that I was ordering her mother to bring her back to Arizona if she did not increase her weight by five pounds in the first month that she was home. As a parting gift I gave the girl a recipe for cinnamon pie, which my mother had invented years before I was born while running a boarding house for a mining camp in the Sierra Nevada mountains. When my patient reached home, she found a letter from me stating that I would like to have a copy of her school picture next September. There was also a very concise but emphatic statement that the question of her weight was one that belonged properly to her and her conscience, and nobody else need know it.

R: When the patient requested a photo of herself sitting on your lap, the nature of her parental transference onto you becomes obvious. Temporarily you become parent to this entire family. Your parting gift of a recipe for cinnamon pie is actually a kind of posthypnotic suggestion for a continuation of the pleasures in eating. Your immediate letter to her when she returned home

requesting her school picture next September is an obvious way of extending your therapeutic influence over her for a more extended period of time, to reinforce her new eating behavior. At the same time you place her in a double bind by telling her that her weight was a matter of her conscience, and nobody else need know her weight. You are again utilizing her strong conscience as a metalevel controlling her own behavior, even though you have had a hand in initiating it.

Six-Month Followup

E: I received the school picture in September, and she was a reasonably well-nourished fourteen-year-old girl. I received a Polaroid picture of her in a bathing suit, vacationing in the Bahamas at Christmas time, and she appeared to be a very attractive, well-nourished, strong, athletic girl. I still receive long, well-written letters from my patient, and there is always an indirect mention made of something edible in her letters. On the last occasion she stated that she thought my idea of having friends plant a tree as a way of noting my seventy-fifth birthday was an excellent one, and that she was going to plant a plum tree in the family garden in honor of my seventy-fifth birthday.

In the summer of 1974 she wrote a long, detailed account of the family's month-long trip around Europe, and she sent me a Christmas package of cookies which she said was traditional in her family.

I know of no other way of treating anorexia nervosa patients satisfactorily and rapidly. My first measure, of course, is to make clear to the mother or father, or both, that the therapy is going to be socially oriented, that the emotional and social needs will be the prime consideration, and that while I may be seemingly offensive, there is a worthy principle involved.

To initiate this type of therapy you have to be yourself as a person. You cannot imitate somebody else, but you have to do it in your own way.

Selected Shorter Cases: Exercises for Analysis An Itch for Life

R: I have a patient who appears to be a deep-trance subject. As soon as I begin an induction, he immediately falls into a deep trance - so deep that he drools and shows no evidence of being able to give ideomotor signals until I begin to wake him up. He has an itching problem. He is a very successful young attorney who just wants to resolve that one psychosomatic complaint. He wants fast therapy. He does not want to fool around with a lot of insight, he says.

E: He goes so deeply in a trance that you can't do anything with him. So what part of the itch does he want to keep?

R: You feel the patient is afraid too much will be taken away?

E: Yes, he is protecting himself by going so deeply into trance. So you must not make the mistake of trying to take too much away. He's come to you with the problem of his itch, but he does not want it all removed.

R: How would you approach this problem, then? By letting him have a smaller itch over a more circumscribed part of his body or a less bothersome itch?

E: I'd say, You're troubled by this itch. Naturally I don't know exactly what it is. I'm certain that you want *your itch for accomplishment to be kept. Your itch to do things can be kept. In fact, there are a number of itches that you want to keep. Any itch that you want to keep - be sure to keep it! Also let's be sure that you get rid of any itch you are willing to lose but no more than you are willing to lose*.

R: What itches could he possibly want to keep?

E: An itch for political power, political position, for wealth, for sex! Itch is a folk word with many connotations about human desires and motivations.

R: I see! If I try to take away his itch, it could be taking away an important aspect of his personality. He is a dynamo who works sixteen hours a day!

E: He has a big itch! Never forget folk language! You should always recognize how the folk language is related to symptom formation.

R: That's fascinating. He was actually referred to me by his girlfriend, whom I'm also treating for a similar problem of itching. She is a dynamo type also.

E: She must be another itch he has.

R: It may be that the folk language of itch is treated literally by the right hemisphere, which then translates it into a psychosomatic process.

Folk language and the unconscious; Need for an individualized patient-centered approach; Structuring a therapeutic frame of reference.

Symptom Resolution Within the Self

A ten-year-old girl was brought to a lecture that the senior author was to present to a medical group. The parents requested that he use her as a demonstration subject for hypnosis, since that was the only way she would agree to see a physician. Noting that the girl was excessively clothed and that she was wearing gloves over her gloves, the senior author asked this girl if her parents had stated matters correctly. She stared at him intently for some moments and then nodded her head. She was told that the senior author did not understand the situation. Her explanation was most informative of her attitude: I'm afraid. I don't want you to know what I'm afraid of. If I go to a doctor's office, he will try to make me tell or he will make my parents tell. I'm not ever going to let anybody know. She was instructed, Without telling me what, just tell me how, so I will know if you are afraid of something you see, or hear, or think or whatever you can tell me. After some thought she answered briefly: I don't want to get dirty. The general assumption was that the problem concerned a fear of contamination or a misophobia.

Because of such guarded behavior on her part the conclusion was reached that it would be well to inquire in what manner she would be willing to accept therapy. On that, too, she had remarkably restricted ideas. Her demand was that therapy be done by hypnosis (whatever that word meant to her), that the senior author was in no way to know the informative details of her problem, that therapy had to be done in such manner that it would not be recognizable as therapy - that is, there would be no talk like a doctor who take's care of crazy people, just talk like when you visit - and that to ensure this she would act as a demonstration subject because a good doctor doesn't tell people anything about patients, not even that someone is a patient." (There was no opportunity to ascertain how she had devised her plan or what ideas had been presented to her before meeting the senior author.) Her parents did explain in her presence that she had forbidden them to give any information. She was asked how this help could be possible, dressed as she was, so carefully. Most earnestly she answered that she would go immediately to her hotel room and dress appropriately for a public appearance if the senior author agreed that she could have a chair that had not been sat on that day and if he agreed not to touch her dress. She was told that her wishes would be respected.

At the time of the lecture she came to the speaker's platform demurely, with her arms rather awkwardly held so that her hands did not touch her dress. Noting this, an available armchair was indicated to her, and she sat down and faced the audience with her arms resting on the arms of the chair. A discussion of hypnosis for children was presented, and then the senior author turned to her to induce hypnosis. The technique employed was exceedingly simple. The lecture and the audience provided a background of prestige for her. She was told to extend her left arm at shoulder level, with a slight dorsiflexion of her hand so that she could see her thumbnail. She was instructed to fixate her gaze on it, to see it seem to get bigger and bigger until it filled her visual field, and then, as it grew in size, she was to bend her elbow very, very slowly, bringing her hand ever closer to her face. As her hand came closer and closer, she was progressively to go into a deeper and deeper sleep until finally, when her hand or fingers touched any part of her face, she was to be completely sound asleep with her eyes open, seeing nothing, feeling nothing, hearing nothing, except the senior author.

Within a few minutes she developed a profound somnambulistic trance state, and the various phenomena of deep hypnosis were systematically demonstrated.

During the entire time after first seeing the girl, before the luncheon and during the lecture, the senior author had been frantically searching mentally for some kind of a therapeutic approach. Since the month was September, the thought of Thanksgiving, Christmas, and New Year's Day came to mind, and these suggested the possibility of a birthday. Hence, as she sat before the audience in a deep trance, she was asked if she would be willing to tell the senior author her birthday. She nodded her head affirmatively and said, Yes. She was asked to name her birthday, and she gave the date as December 29th. This date immediately suggested a feasible plan.

The simple statement was made that while she might have hopes, she did not, at so early a time as September, know what birthday gifts she would receive. She could hope and hope, it was conceded, but she could not possibly know what her birthday presents really would be. Yet there could be something awfully nice, just wonderful, something that she wanted very badly, something that would be very special, even too important for her as a person to be just a

Christmas gift. It would have to be a birthday gift. Of course she might not get it because she would have to do a lot of awful good thinking so she would know what she surely wanted most of all. And what might this present really be? It might be something she could do herself, that she could learn, like the best marks of all the students in her school, or learning so slowly and carefully to knit a whole dress for herself, or how to sew a complete dress for herself. But it could be any special, special thing that she wanted, wanted awful bad. Certainly the senior author couldn't know - in fact, all that he knew was that he was very certain that her birthday would be her eleventh and that she would be leaving the little girls and becoming the kind of a big girl she wanted to be.

Then, under the guise of merely presenting to the audience the topics of hypnotic amnesia and posthypnotic suggestions, a series of statements was made to the effect that posthypnotic suggestions, if there were a purpose to be served, could be given to a subject to effect a total amnesia for all trance events and experiences; that one could tell the subject who wished to achieve some particular goal of psychological or emotional importance that there could be an ever-increasing feeling of conviction, of certainty that the desired achievement would come to pass; that day by day, week after week, there could be a mounting feeling of unidentified expectancy, a feeling of intense, pleasurable tension to the effect that some change was slowly, progressively taking place within the self which would become known and fully realized at any chosen time or on the occasion of some special event. All of these statements were presented as seemingly explanatory remarks to the audience, but to the subject's ears they were posthypnotic suggestions. Yet even her father, a professional man, and her mother, a college graduate, sitting in the audience expectantly awaiting some definite therapeutic suggestions, did not grasp the pointedness for their daughter of what was being said. After the lecture, with much concern, the father - in the absence of his daughter, who had been rather quickly dismissed following the remarks on amnesia and posthypnotic suggestion and who had left the auditorium in the company of her mother - asked worriedly when the senior author proposed to do the therapy. He was urgently admonished that the therapy had been done, that he must warn his wife not to discuss anything at all about the lecture or the meeting of the senior author by the daughter. Instead they were to follow a program of silent, watchful waiting.

As was learned later, one month after her birthday, the girl gave her father permission to write to the senior author to tell him that she was no longer afraid, that after the lecture she got a funny feeling every time she was afraid that something nice was going to happen to her. This feeling grew progressively stronger until her birthday on which day she awakened early and aroused the entire household with almost hysterical shouts of It's gone, it's gone, whereupon she had put herself to test in a great variety of ways. He went on to explain that she had forbidden him to write the news to the senior author but that when a month had elapsed, she gave permission but forbade him to give any description of her problem. She insisted that, since it was over with, all gone, there was no reason even to think about it, that the only important item of news was the fact of her recovery. He pleaded with her to let him write more but she was adamant until he raised the question of telling the senior author a bit about her behavior from September to her birthday. After considerable thought she agreed but stated she would want to see the account before it was mailed. He began with the above account, stating that he and his wife had noted a slow progressive change in the girl's behavior. Her depressive behavior, her outbursts of anger, her general impatience and her tense anxieties progressively diminished. She began crying less

until by December she had ceased entirely to cry at frequent unexpected intervals. Her extreme caution about clothes diminished and she began running to the door every time the doorbell rang or the postman came as if she expected something. They also noted that more and more frequently she would pick up chair cushions and look under them, feel behind the books in the bookcase as if looking for something. Whenever she was asked by her siblings what she was doing, she would answer, Oh nothing, I just thought maybe something was there.

Her school behavior also changed progressively. She no longer had violent emotional outbursts if the other children accidentally violated her taboos - they had learned to avoid her through distressing experience ever since the sudden onset of her trouble, which had been in April of the year the senior author saw her.

Three years later a pert young lady approached the senior author at a medical meeting and asked, Do you really think you can hypnotize me? The reply was made, I think you can learn to go into a trance. To this she answered, That's just about what you told me before, and laughed merrily as the senior author scrutinized her face unrecogniz-ingly. Then she added, I only wear one pair of gloves now when I do wear gloves. Now you know me. The senior author immediately agreed and inquired about her father and mother and waited hopefully and silently. She studied his face, then remarked soberly, No, really, I can't tell you except to say it's all gone and many, many thanks. She seemed genuinely regretful not to be more informative. Her father was encountered and, after greetings, shook his head, stating that the taboo of disclosure still held, but that her recovery remained a pleasurable fact.

Interspersal approach; Indirect ideodynamic focusing; Initiating unconscious searches and processes; Expectancy; Hypnotherapy without the therapist knowing the patient's dynamics; Indirect hypnotic amnesia and posthypnotic suggestion; associating fears with positive expectation; Progressive therapeutic change.

CHAPTER 7

Case 10 Memory Revivication

Resolving a Traumatic Experience

Part One: Somnambulistic Training, Autohypnosis, and Hypnotic Anesthesia

Mrs. F. gave birth to her first child with caudal anesthesia so that she could participate as consciously and as actively as possible. She felt, however, that she had still missed an important aspect of participation in the birth process. For some reason she could not remember much of what had happened. Three months after the child was born she came to Dr. Erickson with a request that he use hypnosis to help her recover her memories of giving birth to her child. Dr. Marion Moore (M) was a participant-observer in this session. The senior author begins this first session by facilitating a therapeutic frame of reference for memory recall as follows.

Suggestions for Recovering Memories: Truisms Covering Many Possibilities of Response

E: To uncover that memory and return it to you is not likely to occur all at once. What is likely to happen is that you'll remember a little bit here and next week a little bit there. The following week some more of the first part. The following week it slowly builds up in a regular fashion. And then some day the whole thing will straighten out.

R: You begin with a series of psychological *truisms* about how we do in fact tend to recover memories piece by piece over time. These suggestions, given in the form of educational directions, are actually so general that they cover *many possibilities of response.* You are giving her unconscious the freedom to work in its own optimal manner,

F: Could you explain simply why the mind works like that?

E: It's like other learning processes. Why is it that babies tend to learn certain words first, yet they always learn other words in different orders? In your own experience: Why are there always certain sentences in a chapter that you clearly remember after the first reading? You select certain things. Next time you read it you get a lot more, but your first reading was highly selective. You can't know and I can't know-nobody can know - just how *you are going to remember any one.* [The senior author gives a number of examples of the disorderly way people go about recalling memories in everyday life. He illustrates this further by asking her to recall what she had for dinner last night, thus validating within her own immediate experience the fact that her recall comes out in a piecemeal, out-of-sequence order.]

R: You answer her question about why the mind works like that with what appears to be a straightforward lecture about the process of learning. You carefully insert a rhetorical question or two about her own early learning and memory processes to evoke her own unconscious associations, and then add a series of examples of how memory works in others. You are not making any demand on her at this time. You are, rather, engaged in a process of ideodynamic focusing. Your general discussion about early learning and memory is automatically evoking ideodynamic responses within her on an unconscious level. Some of these ideodynamic processes may be already intruding into her consciousness in the form of her early memories, or they may remain on an unconscious level at this point. Your simple discussion of these processes, however, tends to evoke or prime them for a vivid conscious experience if you ask for them later during trance. Otherwise, as you have already suggested, the memories she wants may appear piece by piece over time.

E: Yes, I'm emphasizing her own natural memory patterns, - rather than having her rely on some way of remembering she was artificially taught - when I say she can't know and I can't know. Notice the interspersed suggestion, *you are going to remember."* Consciously she does not hear that direct suggestion because her conscious mind is focused on the how that precedes the direct suggestion, *you are going to remember.*

Indirect Hypnotic Forms Preparing for Trance Induction

E: All right, how do you think I will induce a trance in you?

F: Well, I know there is a way by counting one to ten, I believe. I know very little about it.

R: You begin this trance induction with an indirect form of suggestion: the question, how do you think I will induce a trance in you? This question already *implies*that you will induce trance; it's now only a question of how. The question tends to evoke whatever understanding she may have of trance induction so you could possibly utilize it. The question also respects her life experience and individuality; she has an opportunity to express her knowledge and possible preferences. As such, this question tends to mobilize her good will and an *acceptance set* for whatever follows.

Trance Induction via not Knowing and not Doing: The Early Learning Set Induction: Unconscious Conditioning

E: Will you sit back in your chair with your feet flat on the floor and your hands on your thighs. The hands not touching each other, and just look at
one single spot here.
You don't need to talk.
You don't need to move.
You don't even need to listen to me.
Your unconscious mind is close enough to me
to hear me.
And that's the only important thing.

Now there are various changes
that take place in you.
Your heart is beating at a different rate.
Your breathing has changed.
Your reflexes have altered.
And you are doing the same thing
now that you did when you first went to school.
You looked at letters of
the alphabet.
They seemed impossible to learn.
But you did learn them.
And you developed a mental image
of the letters
and the numerals.
And you developed a mental image of each of them in various forms that
stayed with you for the rest of your life.
You have looked at that one spot long enough so you have a mental image,
and you do not know where it is in your mind.
You can close your eyes
N. . .O. . . W

E: When she responds initially by sitting back in her chair with feet flat on the floor, she is saying to herself that she will go *into trance.* These initial adjustments allow her to make that important suggestion to herself rather than my telling her. It's always much better to have patients make the important suggestions to themselves.

R: You now embark upon your favorite form of trance induction via eye fixation and a number of indirect hypnotic forms that are effective precisely because no one could really argue with anything you say. The patient is lulled into *not knowing and not doing* (need not talk, move, or even listen) to *depotentiate her conscious sets.* A *dissociation* is facilitated by your emphasis on her unconscious functioning as a subtle form of the conscious-unconscious double bind.

E: Not needing to listen to me is an indirect way of emphasizing that it's her own personal experience, not mine.

R: You then *ratify* the process of trance experience as an altered state by pointing out how physiological changes have taken place (heartbeat, breathing, and reflexes). You conclude this initial stage of trance induction with the early learning set (Erickson, Rossi, and Rossi, 1976) that tends to evoke ideodynamic aspects of early childhood learning, when so much was absorbed on an autonomous or unconscious level. These early learning patterns may now be activated for learning trance experience, which must also proceed on as much of an autonomous level as possible. You then precipitate eye closure with the direct suggestion to close her eyes N . . . O . . . W said in a slow but quietly emphatic and insistent manner. This particular vocal emphasis now acquires the value of an unconscious *conditioned stimulus.* The next time you use that low tone of voice with similar emphasis and insistence, she will tend to enter trance but not really know why. If you later use the word now to awaken her, you will use a clear, quick, bright, and louder tone

of voice that will acquire the value of a conditioned stimulus for awakening.

Trance Deepening via Contingency Suggestion: Pause as an Indirect Suggestion

E: And with each breath you go deeper and sounder in the deep hypnotic sleep.

[Pause]

Now you know why
you want to go into a trance.
You do not fully understand why some of that memory escaped you.

[Pause]

R: You are using a contingency suggestion when you now facilitate trance-deepening by associating deeper trance with an inevitable behavior - breathing.

E: I pause after telling her to go deeper and sounder" because that does take time. The pause itself is an indirect suggestion to do that now.

R: You then further motivate her for deepening trance by reminding her of her purpose in seeking hypnosis. You thus utilize her own motivation for deepening trance.

An Associational Network Facilitating an Unconscious Search for Lost Memories

E: But the mental images that you formed
in kindergarten
are still within your mind.
Things long forgotten
still have
their mental images in your mind.
You can lose learnings by the loss of brain cells.
But you haven't lost the brain cells concerned with your delivery.

[Pause]

And those mental images belong to you,
and you can enjoy getting them back.
And I think the best way of getting them back
is doing so by getting one small one and being completely delighted by it.
Not asking for more,
but just enjoying the pleasure

and delight of that one little memory.
And the next thing you know
you'll get another little memory that will give you a great deal of pleasure
and delight.
And doing it this way
you will build up your pleasure and comfort and ease
very rapidly.
Not rapidly in time but rapidly in force,
in strength.
And then some day you'll realize
you really do have all of it.
And when one uses the unconscious mind,
one does it
at the rate of speed that belongs to the unconscious.
Your unconscious knows how fast it can work,
how fast your conscious mind works.
And your unconscious will know how to feed that memory back to you.

E: I now follow up on my earlier remark about that memory escaped you by pointing out how even earlier mental images are still within your mind. This implies that the escaped memory is still within and available to her.

R: You are now building up an associational network wherein you utilize the early learning set you evoked earlier as an *analogy* or *ideodynamic process* that could facilitate her conscious mind does not know how to do it (that's why she came to therapy). Analogy and/or ideodynamic processes thus function here as indirect hypnotic forms to facilitate that search on an unconscious level. You then leave it to her *unconscious to mediate the process* in a manner that is most suited to its own functioning (fast or slow, a lot at once or a little, and so on).

E: I admit to her that there is a way of losing memories by a loss of brain cells, but I affirm that is not the case with her.

R: You thereby pick up some doubts she might have about being able to recover her memories, and depotentiate them.

E: When I affirm that the mental images belong to you and you can enjoy getting them back, I'm referring back to my earlier remark about how they escaped you and the implication that she deserves to get back what belongs to her. I then emphasize the delight one little memory can give her.

R: That can reinforce her so that she will tend to have more and finally a chain of recovered memories.

E: Someday you'll realize you have all of it implies a *noncritical acceptance* of each small bit of memory as it comes. I'm attempting to rule out self-criticism.

R: That conscious self-criticism can so limit the spontaneous creativity of the unconscious.

E: Yes, I say it belongs to the unconscious and the unconscious knows how fast it works. I then contrast that with how fast your conscious mind works, thereby separating the conscious and unconscious.

R: You emphasize the separation of conscious and unconscious to make sure she leaves it to the unconscious rather than try to work on it with the more limited means of her conscious processes. That is the essence of your hypnotic approach: *depotentiating the conscious mind's limited means and reinforcing unconscious processes with their greater potentialities.*

E: Yes, and the separation is stated in such a way that it has to be accepted because what I'm saying is true.

R: Hypnosis is not a means of directly programming people to do things in one way. With billions of neurological connections in the mind it is terribly presumptuous to try to program people.

E: It is a very uninformed way.

R: We are allowing the infinite diversity of the unconscious to come forth rather than trying to program one idiotic idea or point of view we may have. There are infinite patterns of learning and ways of doing things. Our approach helps people unlearn their learned limitations.

Surprise and Pleasure to Reinforce Unconscious Functioning: Safety Suggestions

E: Many times in the past you have been taken by surprise.
And before you could think of what to do,
you just did it
because your unconscious knew
before you did.

[Pause]

And this is a situation for you
to be willing to let your unconscious mind
return that memory to you
in the way it knows you should get it back.
There is no hurry.
But there is a pleasure awaiting you.

[Pause]

R: You use surprise as another indirect hypnotic form that will tend to *depotentiate the limitations of her conscious sets and habitual attitudes* that may be blocking her memories. You

reinforce this by again emphasizing the central role of the unconscious being allowed to work in its own. You continually suggest that pleasure and enjoyment will accompany the *unconscious search and processes.* This is in part a truism and in part a means of motivating her further. It would be a significant research problem to determine if, in fact, such suggestions for pleasure are ideodynamically mediating further reinforcement by activating the positive reward centers of the limbic system.

E: If there are any resistances or hidden trauma associated with these memories, I'm using a safety factor by suggesting that her unconscious will return that memory to you in the way it knows you should get it back. I then balance a negative and a positive in the next suggestion, There is *no* hurry . . . there *is* a pleasure awaiting you. The negative emphasizes the positive.

Separating Conscious and Unconscious Processes: Trance Awakening and Ratification: Training in Posthypnotic Suggestion

E: I'm going to have you awaken shortly
for a lesson
in enjoying what your unconscious can do for you.
When I awaken you,
I want you to have a very profound feeling of comfort, as if you had been
sleeping for eight hours.
I want you to enjoy that.

[Pause]

Now you can start thinking
about counting backward from twenty to one,
waking up one-twentieth of the way at each count.
And you can begin counting backward from twenty to one, awakening at one.
And begin the counting *now*!

[Pause as Mrs. F silently counts to herself and opens her eyes and begins body reorientation in twenty seconds]

E: I emphasize that I am going to awaken her because I don't want her unconscious to awaken her. It's the job of her unconscious to turn up those memories. It's my job in association with her conscious mind to awaken her. I carefully separate the conscious and unconscious and keep them separate.

R: You begin the process of awakening her with a subtle posthypnotic suggestion that is very easy to accept. Her trance experience up to now has given every appearance of the deeply comfortable, receptive sort that is sometimes difficult to distinguish from sleep. You therefore *utilize* this to ratify her trance on awakening. Whatever behavior the patients manifest during trance (concentration, restlessness, emotions, etc.) can be used to ratify trance with a posthypnotic suggestion that allows them to respond with some expression about it upon awakening. This is

your initial approach in training her to follow posthypnotic suggestions. You finally awaken her with that now! said in that bright and alert tone that will become an unconsciously conditioned stimulus for awakening.

Posthypnotic Suggestion Ratifying Trance: The Patient's Experience as the Focus of Attention

F: Hi! How was I? Oh, I felt like I went to sleep! You know? Like I went to sleep. That was strange.

E: A beautiful demonstration.

F: Did I go into a trance like I should have?

E: How do you feel?

F: It was sleep yet it wasn't sleep. It was like a borderline to sleep.

E: How do you feel physically now?

F: Much more relaxed. Much more at peace. I feel much more with it. I heard your voice, and it became a little fainter, but it was there in the background.

E: But you ceased to hear individual words and sentences?

F: Yes, just a voice.

E: Did you hear my cassette recorder start and stop?

F: No, I did not hear any other thing.

R: Her first words on awakening are an obvious response to your posthypnotic suggestion to feel as if she's had eight hours of sleep. She is also ratifying trance at the same time. She describes the comfortable, quiet, and receptive type of trance where no conscious effort is being made in any direction. This is in sharp contrast with the deeply searching, concentrated, and furrowed brow that was characteristic of X's trance (sweating case). The dissociation wherein F could hear the therapist's voice in the background but not the individual words and sentences is very characteristic of trance.

E: My voice in the background is where I want it to be. It's in the background of ***her***experience. Her own experience is in the focus of attention.

R: You evoke the patients' own inner experiences as the therapeutic factor so that they don't hear irrelevant things (such as the cassette recorder). This is the opposite of so many therapists who insist that the patients focus on the therapist's words and views.

E: I asked her, How do you *feel*? because I did not want her *thinking*.

R: It can be entirely valid to *feel* as if she had eight hours of sleep, but it would be a falsehood to ask her to really *think* she had had eight hours of sleep when you both know she has not. You are always careful to avoid anything that would cause disbelief and a loss of faith in the validity of whatever you say.

E: I always distinguish between thinking and feeling: Thinking can be valid but it's limited; a feeling can be anything even though it's an illusion from a rational point of view.

Somnambulistic Training: Indirect Posthypnotic Suggestion for Trance Induction by Catalepsy

E: Would you like a surprise?

F: OK what is it?

[The senior author silently reaches over and touches her right hand with a very slight guiding motion. Her hand lifts and remains cataleptic, suspended in midair.]

E: Close your eyes and go to sleep.
And you can really feel pleased,
and happy,
and rested.

E: In her first trance I mentioned how she'd been taken by *surprise* many times in the past when her unconscious knew something before she did. That was an unrecognized post-hypnotic suggestion that is now being used to induce this second trance with a surprise.

R: This trance induction by catalepsy (Erickson, Rossi, and Rossi, 1976) is also a way of deepening her hypnotic involvement with a nonverbal approach. You then deepen the trance by utilizing the sleep . . . happy . . . and rested experience, which you now know she is very capable of experiencing. You are beginning somnambulistic training by giving her many experiences of entering and awakening from trance. What other means have you for facilitating the somnambulistic state?

E: It's like learning anything else in life. The first time you read a textbook, you may not understand much; after you've read it two or three times, it begins to make *sense. Rehearsal of trance, posthypnotic suggestion, and further hypnotic training are all being given at the same time to develop somnambulistic behavior.*

Trance Awakening with Open-Ended Posthypnotic Suggestion

E: And if you wish,
you can leave your right arm where it is

after you awaken.
And you can begin counting backward from twenty to one, awakening at one.
And start the counting *now*!

[Mrs. F awakens with her arm remaining cataleptic in midair.]

R: You now give a very open-ended posthypnotic suggestion to leave her hand there if she wishes. This open-ended approach is fail-safe and tends to evoke an *acceptance set* by allowing the patient to express her own individuality. It is also a means of further assessing to what degree she is willing and ready to experience further hypnotic phenomena.

Trance Ratification via the Patient's Own Experience

F: Umm. What is my arm doing there? What is this? [She withdraws her arm from its cataleptic pose.] Why was that up in the air?

E: Do you realize you've learned how to go into a trance?

F: I was thinking about that and just wondering if I have grasped enough to do this myself. I'll go home and try it unless you'd rather I not.

E: I don't answer her question directly but ask her a question that would evoke her own experiential learning.

R: Your question is an indirect hypnotic form that makes her search within and answer her own question about her hand in a manner that tends to ratify her experience of trance. Her hand does not usually act that way; therefore she must have been in trance. Her response of wanting to do it at home is now a direct acknowledgment of having experienced trance.

Third Trance: Induction and Posthypnotic Suggestion for Learning

E: You never waste a good skill on unimportant things. You use it only on important things. You would not use hypnotic anesthesia for a pin-prick, but you would use it for childbirth, surgery, for the pain of a broken leg.
Now do you want to see what you have learned?

[The senior author again induces an arm catalepsy by guiding her arm upward. Mrs. F blinks and closes her eyes and evidently goes into a trance.]

And you can leave your arm there and recognize what you have learned
after you awaken.
And you can awaken by starting counting now.

[F awakens with her arm still cataleptic.]

F: That is ... oh!

[F puts her arm down.]

R: You respond to her request for what amounts to autohypnotic training by first cautioning her to use trance only on important things. Why?

E: I'm forbidding any unimportant experimentation. The important thing is to get her memory back - not to see if she can levitate her hand.

R: Trivial experimentation tends to blur the distinction between the trance and awake state and lessen the dissociation between them, which in turn lessens the effectiveness of trance. After inducing the catalepsy, you give an important posthyp-notic suggestion that she can leave her arm there and recognize what she learned after awakening. She does in fact awaken with the arm still cataleptic and then apparently has some inner realization and only then puts her arm down. Presumably she's learned an association between hand levitation and trance.

Fourth Trance: Autohypnotic Training via Training and Expectancy

E: Now suppose you raise your hand.

[F lifts her hand until it remains posed in balanced tonicity (catalepsy). She closes her eyes and evidently enters trance.]

R: In asking her to lift her own hand this time, are you placing trance induction more under her own control as a stage in autohypnotic training|

E: I did not tell her to go into trance. When you tell someone to raise or extend the hand, they are going to *expect* something. You're using that expectancy learned in everyday life.

R: And what else is there to expect in this situation except trance? You have built an association between hand levitation and trance so that she can expect and does, in fact, go into trance entirely on her own. This may look superficially like a process of conditioning (and it may be in part), but it's the element *of expectancy* as well as her own *motivation* for trance that leads her to experience it here.

E: I didn't define it as trance. I let her own experience define it.

Implied Directive to Ratify Trance: The Careful Study of Communication by the Therapist

E: And when you have recognized that you are in a good trance, you can tell yourself about awakening.

[After a few moments F awakens and reorients all on her own.]

F: Um! My word! I'm taken sort of by surprise by all of this.

E: A pleasant surprise.

F: The mind is an unbelievable organ, isn't it! This is wonderful.

E: All right. Now you know you can lift your hand and go into trance, and when you have been in a trance sufficiently, your unconscious mind can tell you to awaken.
Now you know you can do that. You have just had that experience.

F: Yes.

R: You now use the implied directive as a means of having her recognize, explore, and validate her own trance experience. It is very important in autohypnotic training to give the patients an opportunity to recognize and ratify their own trance experiences.

E: When she says, I'm taken ... by surprise, you know she's following my pqsthypnotic suggestion for a surprise. The validity of the experience is expressed in her own words, The mind is an unbelievable organ. . . This is wonderful, not mine.

R: Above all, hypnosis is experiential learning rather than intellectual or abstract knowing.

E: I want you to notice how connected everything is even though it's all impromptu. *It is a language I've learned, a careful study. I know all the articles of speech and I know the meanings of all the words. Because I learned it carefully, I can speak it easily.*

R: It seems casual but it's well-rehearsed in your mind.

Generalizing Successful Hypnotic Experience For Problem Solving

E: You can also know now that your unconscious can do what is necessary about that memory. And you can trust it to do it in the right way.

F: Yes. Is there ever a situation when you're in the trance and cannot come out of it? Like the door closes and you cannot get it open. [Erickson gives examples illustrating that an individual in trance can awaken at will for any good reason.]

R: You illustrate the potency of her unconscious in a concrete way (via entering and coming out of trance) and then make this important generalization that her unconscious can also facilitate memory recall. That is, you immediately utilize her successful trance experience as a model of how the unconscious can contribute to her behavior and how it can facilitate a solution to her problem.

Unconscious Protecting the Individual

E: Your unconscious knows how to protect you.

F: There is some protection? I thought the unconscious was completely open?

[E gives examples of how the unconscious can protect the individual.]

E: Your unconscious mind knows what is right and what is good. When you need protection, it will protect you.

R: It is one of the most common misconceptions of hypnosis that you lose all your control and faculties. Hypnosis is actually a very selective form of attention.

R: In one of your earliest research programs you demonstrated that it was not possible to force people into destructive behavior with hypnosis (Erickson, 1932). Do you still believe that is so? Does the unconscious *always* protect the person?

E: Yes, but often in ways that the conscious mind does not understand.

Surprise and Indirect Suggestions for Caudal Anesthesia

[A general discussion about childbirth with hypnosis takes place. In a surprise move Erickson suddenly suggests the possibility of Mrs. F experiencing a caudal anesthesia as follows.]

E: By the way, did you know that you could produce your own caudal N . . . O . . . W.

F: Well, that would take a lot more time though, wouldn't it?

R: The general discussion about childbirth seems innocent enough, but it's actually a means of structuring a new mental framework through indirect ideodynamic focusing; by discussing childbirth in the most general terms her unconscious will automatically initiate many ideodynamic processes she actually experienced in her recent childbirth experience. These include, of course, a caudal anesthesia induced by chemical means. Her unconscious has a record of this experience, and when you ask her the *question,* did you know that you could produce your own caudal N ... O ... W? you are using two indirect hypnotic forms to induce trance and initiate an *unconscious search and process* that may help her reexperience her caudal anesthesia as a hypnotic response: 1) N . . . O . . . W spoken in the slow, low, insistent manner tends to reinduce trance as an unconsciously conditioned response; 2) the *question*initiates the *unconscious search and processes* for the ideodynamic memories of her chemical caudal anesthesia. This all happens automatically (hypnotically) even though her mind doubts, that would take a lot more time though, wouldn't it?

E: You did not recognize the element of surprise as a third factor.

Surprise and Vocal Cues for Reinforcing Anesthesia

E: Now you listen to me because you are going to be very surprised *because you can't stand up.*

[Mrs. F looks a bit startled, and her body remains perfectly still for about fifteen seconds as the senior author continues.]

E: You don't know how to stand up, do you?

F: Well I did when I came in here.

E: *You've got a caudal!*

R: Since she did express some doubt, you then reinforce your suggestions with more emphasis on the *surprise* aspect of unconscious functioning (particularly since she earlier appeared to like this surprise aspect), and your slow, low, insistent vocal cues (in italics) which are by now well associated with hypnotic responsiveness.

Removal and Ratification of Hypnotic Response

[Pause as Mrs. F remains motionless for another fifteen seconds, then Erickson removes it as follows.]

E: Now you can move!

F: [She looks a bit incredulous and finally shifts her lower body a little.] Is this a joke or is this real? Because with the caudal the only thing I could move was my big toe.

E: That's right. You see, I know what a caudal is, and when I give a hypnotic suggestion that you cannot stand up, you lose the ability to use your leg muscles.

F: Oh, boy! What an education I've gotten today!

R: You let her remain immobile for only eighteen seconds. Is that because you sensed she doubted her hypnotic response and may have broken out of it by testing it too much?

E: You develop a sense for these things. I do know that I wanted to stay away from any dispute about her big toe.

Protecting and Further Ratifying Hypnotic Responsiveness: Unrecognized Posthypnotic Suggestion Via Generalization

E: Now don't try to explain your learnings to anybody. They belong to you and they are special, and when your child starts growing up and hurts his arm, you can remember how I told you gently, You can't stand up. And you couldn't. You can tell your child he is going to feel all right now. You say it and you mean it. Your sincerity and your expectancy will

cause that child to accept the suggestion, and his arm won't hurt. [The senior author now tells a story about how he taught a physician to use *the surprise technique of anesthesia*.] A farmer came into the emergency room with a serious wound, shouting over and over in a state of panic, Doctor, you've got to help me! Doctor, you've got to help! The nurse tried to get the farmer seated, but he just kept pacing back and forth and shouting. Finally the doctor said, Shut up! Sit down! Stop hurting! I had told the doctor he could do that, and he tried it out. Ordinarily you don't talk to a patient that way. The farmer was so surprised that he did sit down and stopped hurting. That is the surprise technique.

R: You then protect her hypnotic learning by cautioning her about listening to any doubting views from others?

E: Yes. When I associate her current hypnotic learning with *inevitable* things that will happen to her child, I'm extending these learnings into her future as an unrecognized posthypnotic suggestion.

R: You're thereby generalizing her hypnotic learning to future life situations.

E: I now generalize it further with this other story of how I taught a physician the surprise technique of anesthesia.

R: The story also tends to further resolve any inner doubts she may have of her hypnotic response and thus ratifies it further.

Surprise to Initiate Another Unconscious Search

M: Might I add one thing to her memory, as it is going to come in the picture. She is going to have one additional thing that will be a very delightful surprise when she recalls it. It will have something to do with the time of rotation (of the baby's head during the birth process). I'll just leave it at that. It will be the little flower on the icing of the cake.

R: Dr. Moore's suggestion that the patient will have another additional . . . very delightful surprise is a further means of motivating her for a thorough *unconscious search* for the memories she wishes to recover. We will see the truth this suggestion brings forth in the next session.

Concluding Directives for the Unconscious Search: Focus on the Patient's Experience

E: One thing more: Your returning memories will start. What tune did you say the water bag broke?

F: About 6:40 A.M.

E: The memories will start by a sudden recovery of that memory, very intense, and then you can go on to the rest. You see, you weren't asking for the breaking of the water bag.

You are asking for something hours later. Your unconscious will probably pick out the breaking of the water and then go on.

F: Because that was the start of the event?

E: Yes.

F: I remember that very clearly.

[Mrs. F now recounts the circumstances of how her water bag broke and the unexpected suddenness of her child's birth.]

E: You've already outlined to me a memory you didn't know you had. And you are going to find it out.

F: The memory is going to come back in pieces?

E: I don't know how you are going to do it. You may get it back hi one piece, you may get it back backward and not till it is all there will you straighten it out.

M: You might remember the nice things first.

R: Why did you give her these final very specific suggestions for recovering her memories?

E: I'm giving her a base within her own experience. She remembers 6:40 very well, and that can serve as a foundation for the recall of more memories. It's a marker around which she can organize her memories. When she lost her memories, she never really tried to restructure her recall as I'm now suggesting. When she now begins to recount the circumstances of how her water bag broke, she is following my implied suggestion where I've been telling her all along, This is your experience. It belongs to you. I'm only a background. Your own experience is the foreground.

Part Two: Reorganizing Traumatic Life Experience and Memory Revivication

Two weeks after the preceding session Mrs. F returns to report as follows:

F: I had two items that came to me concerning the birth of my child. In that twilight state between being awake and asleep I recovered a vivid, detailed memory I had forgotten of being in the doctor's office. Why it came up I cannot tell you, but it did. The doctor came in the door and asked, Have you felt life? and I said, Yes, since yesterday. The doctor said, That's normal, that's when you should begin to feel life. I then woke up and thought, that's strange, I wonder why I remembered that? My mind seemed to pull it out of its memory bank.

[F reports that a few days after the above she had a more extensive recovery of memories while in another twilight state between being awake and asleep. She recalls being in the delivery room and her doctor being gowned in preparation for the delivery of her child. An edited version of her report continues as follows.]

F: All the details of that particular time frame came to me. Slowly - this has been a very slow process like you said it would be, it wasn't overnight. Very slowly the whole sequence of the delivery came more and more to the fore of my conscious mind. It was very slow over quite a few days. A little more sharper and a little more sharper. And it all seemed to hinge on two days when my mind decided to pull out certain memories or thoughts somehow. How, I don't know. I was surprised. Especially remembering sharply the part about the delivery. It was all related to the recovery of that earlier memory of the visit to the doctor's office, where he asked about feeling life. That's what was important to my mind.

I noticed also I'm more able to put into order the things that I can vividly recall. I can put them in order instead of a hodgepodge with nothing fitting as it should. That's what's transpired since the last time I saw you.

E: And was there any one or few moments during the delivery that became very vivid?

F: The most vivid memory was of those green leg coverings that the doctor wore. I know my mind exaggerated them. They were huge!

[E asks pointed questions, which elicit a train of associations suggesting that F's memory of life in the doctor's office was very important to her and associated with her memories in the delivery room because life was a strong reassurance against many negative and fearful stories she had been told about the dangers of childbirth. These negative expectations had been unfortunately reinforced just moments before the delivery of her child because she heard the painful cries of another woman who had just given birth to a stillborn child. She continues to recount with indignation a number of the hospital's unnatural procedures, such as tying her hands down during the delivery as if she were some kind of wild animal without any sense, and not preparing her for the episiotomy. She was shocked to hear the snip of the doctor's instruments cutting her flesh during the episiotomy.]

Spontaneous Personality Maturation with Memory Recall

E: Do you want to find if you can remember better in the trance than in the waking state?

F: I think I would.

E: Have you noticed any change in yourself as a person since we last saw you?

F: Less anxiety in every way. The more uptight you become, the less well you remember, and it becomes a vicious circle.

E: How much older do you feel?

F: I feel my age. Sometimes I feel fifty, but usually I feel pretty good. That's a strange question, isn't it?

E: You appear slightly older now. Not in looks but in the sound of your speech and manner. The arrangement of your ideas is slightly older.

F: How come? How could I age in a week?

E: Because that memory was important to you, and you were so up-tight that you did not allow all the maturing possible to take place from childbirth. And that, I judge, constitutes some of the reason for your anxiety.

F: Oh, now I see.

R: Having that amnesia could retard a natural process of maturation. Someplace within her she understood that, and thus her concern to recover those memories in as clear a form as possible to facilitate her natural growth process.

E: Her unconscious knew something that she could not even dream and receive consciously. Now you see what I mean by unconscious wisdom?

F: Which is smarter, the conscious or the unconscious?

E: The unconscious is much smarter, wiser, and quicker. It understands better.

F: That's just fabulous isn't it!

R: You begin with a question about whether she would like to find out if she can remember better in trance, you obtain her assent, and then bounce onto this other question about her more mature manner. You evidently saw some behavioral resistance to trance at this point, so you delay trance induction till later.

E: [The senior author recounts clinical examples of how the natural process of personality maturation can be blocked by traumatic experiences that result in amnesias, since the life experience has not been integrated. The deeper meaning of her request to recover her lost memories is now evident: These memories are important for her current and future personality growth and maturation.]

Body Language in Trance Resistance

E: What is your reluctance about going into a trance today? [E noticed that F had her legs crossed]

F: Did I show that to you? I have no reluctance.

E: You have a minor reluctance.

F: Well, boy, you must be extremely perceptive. I don't, What is it that makes you feel this way?

E: I'm not going to prompt your conscious mind. I prefer what your unconscious tells me.

F: I did not notice any reluctance at all. Is it the manner of speech, mannerisms?

E: Don't try to guess it. Your unconscious is doing a beautiful job. It will let you know.
DO YOU WANT TO GO INTO A TRANCE TODAY?

F: Yes.

E: N. . .O. . . W?

F: Okay.

E: [To R] You've seen the answer, haven't you?

R: Yes, I think I do.

E: I didn't say. [To F] Uncross your legs please. [Pause as she uncrosses her legs and adopts the more typical posture for trance induction]
N . . . O . . . W.

[Pause as F's eyes flutter and then close]

Go way deep into the trance.

[Pause]

E: At the end of the last session Dr. Moore suggested she would remember something that would be the little flower on the icing of the cake, but she makes no reference to it in this initial account. Since she has not tried to identify it, she may be reluctant to enter trance where she may be faced with it.

R: I notice she also had her legs crossed, which is the opposite of what you advise during trance induction. She keeps them crossed during your initial effort with the conditional N . . . O . . . W and doesn't enter trance until you ask her to uncross them. Then your N ... O ... W is effective.

Patient Deepening Trance with Hand Levitation

E: And entirely for yourself
in an objective fashion
review everything that you told me,
told us.
Review it slowly, carefully, objectively.
And if you notice any minor deficiencies,
it's all right to correct them.
It's also all right for you to correct them and not to know that you havecorrected them.

[Pause as F's right hand begins to levitate upward very slowly in a barely perceptible manner]

E: She now deepens her trance by raising her own hand so that she can verbalize it without knowing it. She takes care of that by making certain that she goes deeper.

R: She is protecting her conscious mind by going deeper into trance. You offered some protection with your suggestion that she could correct minor deficiencies without knowing it.

Self-Protective Mechanisms of the Unconscious

E: But I do want you to appreciate the ability of your unconscious mind.

[Pause]

The ability of your unconscious mind to perceive things.
And to release them to the conscious mind in
whatever detail
the unconscious considers
best.

[Pause]

And now there is a question I asked you.
And I'm going to try for an answer now.
Before the episiotomy,
perhaps subsequent to it.
But I wonder if before the episiotomy
you had some overlooked, forgotten feeling in your breasts.
You don't need to tell me.

[Long pause as her hand now levitates to about two inches above her thigh very, very slowly]

Your unconscious seems to be
telling me,

not letting you know.

[Long pause as hand continues levitating very slowly]

E: As I get closer to anxiety-producing material dealing with the episiotomy her hand levitates more as a protective device by deepening trance.

R: This appears to be a clear example of the self-protective aspect of the unconscious that you frequently talk about. The unconscious is deepening the trance to protect the conscious mind from knowledge it's not yet ready to receive.

E: Yes.

A Cautious Open-ended Exploration of the Traumatic Aspects of Memory

E: Before you went into the trance,
your unconscious endeavored to tell me the same thing.

[Long pause]

And as far as I can judge,
your unconscious has not yet made up its mind
whether you should know or not.

[Pause]

As I told you last time,
records are made with the brain cells.
The only way to lose those records is to lose the brain cells.
And whether you find all the memories now
or later,
it is not important.
The only important thing is
for your unconscious to see to it that you really
feel comfortable
with all the memories you do have.

[Pause as her hand continues to lift, but her head and body slope downward]

I think it was a surprise to you
to find out
that you slowed up
maturation
in your need
for a more vivid memory.

Your unconscious has done a beautiful job
of giving you that maturity.

[Pause as her head and body slope further down]

Now slowly lift up your head.
Still higher.
And slowly tense the muscles of your back
until you're finally sitting up straight in the chair.

[Pause as she slowly realigns her body, with her hand levitating still higher]

It's perfectly all right not to know
that about your breasts.
It's also perfectly all right

to recover it later.
It's perfectly all right for me to be mistaken.

[Pause]

And you can look
with comfort
upon that
shock
connected with the episiotomy and the forceps.
You need have no regrets about that.
In fact, it is delightful to know

that you could have shock,
surprise,
and resentment
about your hands being tied down.

E: I'm taking all the resentment away from a particular thing (the episiotomy) and I'm focusing it on her hands being tied down.

R: You're giving her unconscious a series of cautious, open-ended suggestions to permit the memories and understanding of her situation to proceed in their own way and time. You also protect her from any misconceptions you may have with your remark about its being all right if you are mistaken. You're giving her own system the authority to declare what is valid for her own experience.

Facilitating new Frames of Reference

E: And you need know
that whatever interpretations were placed by others upon
your behavior,
you know what your behavior really was.
And that if they made an interpretation
you were fighting to get away,
you're psychologically altering
your psychosomatic position
to include forceps
and the altered view
of an episiotomy,
And you are so correct in saying
you heard the snip.
When using the word snip,
let's not dismiss it with that word.
You heard the cutting
like you hear the cutting of cloth,
and it's a very similar sound,
cutting of thick cloth with a large shears.

R: She was traumatized by not being told about the possibility of an episiotomy and thus not being prepared for it emotionally. You're here giving a series of suggestions about how she can now reorganize her perceptions and understanding of her experience. You don't tell her exactly how, but leave it fairly open-ended, to develop an altered view of an episiotomy ; when she used the word snip earlier, it sounded very frightening. Your reassociation of the word to the fairly innocuous sound of cutting cloth, which is in the range of pleasant experience for most women, may help her reinterpret that snip into a more pleasant frame of reference. But it's only a most general example. Your basic suggestion is for her unconscious to reorganize and reassociate that shocking experience into a more palatable frame of reference.

Dimming Irrelevancies and Traumatic Experience

E: Now your unconscious
can eliminate
the intrusion
of the other woman's sounds.
And let them become
the dim sounds,
the dimmed memories.
Your memories have that
pleasant and beautiful vividness
that belongs to you.
And you need to realize
in each first experience,
not knowing

prevents us from noticing
even though we do record.

[Pause]

R: You're here giving interesting suggestions for dimming the irrelevancy of the other woman's sounds and with them the traumatic aspect of her own fears of the dangers of childbirth, going back to the unhappy stories of her childhood. That is, you may be indirectly dimming those fearful images of her childhood so that her mind can now be free to deal with the realities of her current adult experience. You then make an interesting statement of what may be the essence of psychological trauma: The mind recording something it does not or cannot organize because it's a first experience that is overwhelming in some way.

E: Yes.

A Careful Awakening with Posthypnotic Suggestions of Comfort

E: Now straighten up still some more.
Still more. Still more.
Still more. Still more.
Even more. Even more.
Let your head be slowly upright fully.
And now,
as you slowly awaken,
I want you,
as you
awaken a bit at a time,
to increase
a bit at a time
your sense of comfort
and pleasure.
Enjoy life.

[Pause as her head lifts and she awakens, reorienting to her body]

E: All this rather slow and elaborate awakening procedure is to get her away from any traumatic unconscious material that her conscious mind is not yet ready to handle.

R: Yes, and you protect her further with your casual posthypnotic suggestions for comfort. . . pleasure . . . enjoy life.

The Reorganization of Traumatic Experiences

F: You said something that really hit home! The first experience! Because you've never experienced it before, you don't know. It's unknown even though your mind records things,

it's still unknown to you. And it unfolds to you. And that's how a certain mild shock - of a first unknown experience. I don't know why. That really hit home. That really stood out just like that! I don't know whether you intended this, but I saw a calendar that has all the important dates flipping backward and backward. It flipped through real fast all the items which I would consider a day at home. There all of a sudden I was at my living room table. And there were more details that had happened. You know, small things, conversations came to me. More stuff (forgotten memories) came out.

E: That's fine.

F: That's weird, why did that happen?

E: I merely said the right words which you could understand, but understand in your way.

F: Also, all this chaos - and that's exactly what it was, chaos. If you can imagine it, there was only one nurse for that whole obstetrical floor. And she had me to care for and my doctor and the hysteria going on next door (the stillbirth). Back and forth, I'm telling you! The phone ringing! Absolute chaos! Now that's dimmed, all that turmoil. That's what it was - turmoil and noises - and I don't know what-all was going on over next door. That's sort of dimmed. That's sort of taken second place.

R: Second place to your own experiences.

F: Right. And the awareness of what was happening to me is heightened.

E: [To R] Now you see it, don't you?

R: Wow, that's fantastic! Is that characteristic of this approach: The background fades into the background and the relevant matters take a sharper focus?

E: That's right. And psychotherapy would be much easier if everybody realized that.

R: A major function of psychotherapy is to let unimportant things fade into the background and only the relevant things come to the foreground. That's what hypnotherapy does*par excellence.*

E: That's right. And I didn't take hold of all these background things. R: You let them be background.

E: I let *her* render them into the background. She didn't know why it happened, she just knew I said something that *really* hit the point.

R: There is a recording consciousness that is independent of a knowing and understanding.

E: Yes.

R: She describes very well the absolute chaos that led to her traumatic experience and the effect of your suggestions in dimming that chaos so she can now focus on a heightened awareness of what was happening to her. This is an excellent example of your basic thesis that hypnotherapy can lead to a resynthesis and reorganization of unfortunate life experience.

The Person in the Physiological Process

F: I'm curious and tried to do some analyzing on my own. What relationship is there to your question about feeling in my breasts?

E: It's nice to know what you do understand.

F: [F again recites the traumatic aspect of being unprepared intellectually for the episiotomy and forceps, so that she felt herself shaking by the time it was over. The shaking actually continued for hours before it subsided completely.]

E: Dr. Moore mentioned that. Do you want me to tell you the rest of the meaning of that shaking?

F: Well, the doctor said it was normal. I don't know. You tell me, go ahead.

E: You said, I don't know. You tell me.

F: Well, I just know what the doctor said - it was normal. He said it was a release of all the nervous system.

E: He doesn't even know! You are describing it well without even knowing what you are describing. I'm very glad you had the original shaking. I'm very glad you repeated it.

R: This is what Dr. Moore was referring to at the end of our last session as the icing on the cake.

E: Yes.

F: There is a mind involved in all this!

[F outlines her experience of how her mind (thought, feelings, etc.) was very much involved with the birth experience. Even though the caudal anesthesia cut off certain sensations, there was much pressure and rhythmic contractions she could experience. She derides her young doctor's view that it was all just a physiological process.]

E: There is a person involved in it.

F: Right! A personality, so I think that all has something to do with it. It's the release of everything.

E: You want me to tell you how the person is involved? F: Yes.

R: She gives us an excellent statement of the importance of the person and the total personality that is so often ignored in modern medicine.

E: It's so difficult to get many physicians to understand this.

The Orgasm in the Birth Process: Individual Patterns of Knowing and the Resolution of Traumatic Experience

E: Think it over just a little bit. You got so close to it that Dr. Rossi here knows exactly what Dr. Moore meant.

F: [F now launches into another detailed set of recovered memories of the dynamics of the birth process: the way the doctor manipulated the baby's body, the fears and sensations she experienced, and so on. She describes how the baby finally came very suddenly as follows.] When the infant came out, it was like an explosion! I was never prepared for that. I just wasn't prepared! It was a weird feeling - like an explosion. I was dazed! I was absolutely dazed! Really, that explains it, I was dazed!

E: [E tells stories about the joyful shaking people have experienced when they have accomplished an important goal.] And the most beautiful *orgasm* a woman can have is when she gives birth to a baby.

F: That's what I was thinking! That's what I was thinking! It is really! The similarities, I'm not kidding you. The similarities between the two are quite the same and they go hand in hand. . . . The cry of the baby was like music ... I was dazed, I couldn't believe it. [F now recalls many more memories of how she had to educate her young obstetrician about the process of carrying a baby, when it would be due, how much it would weigh, the sex of the child, and other factors in childbirth.] I was always one step ahead of that man.

E: The unconscious mind is very brilliant.

F: Was it my unconscious telling me those things?

E: That's right. There are a certain number of women who really do know those things, including what the sex of the child will be.

F: Why, my unconscious is more tuned in, or what?

E: Apparently you were trained in a *be-yourself way.* Your education never limited your behavior.

F: Well, it's a down-to-earth attitude. R: That allows your natural self to be. F: No pretentiousness that gets in the way of things.

E: Such women see no need for blocking out from themselves. So often you hear people say, I wouldn't even think about that, and they don't.

R: Such people only learn to limit their perceptions and understandings.

F: [F again launches into a good-natured tirade of even more indignant memories about how she wanted to experience a more natural childbirth but was overwhelmed by the modern technology of the hospital delivery. This session finally ends with a general discussion of the interesting natural stages in an infant's growth that a mother can look forward to.]

R: The good-natured quality of her critical remarks is now very different from the fearful and tearful feelings she had when she first hinted at them in the beginning of her therapy. She has not only gained the complete set of memories she wanted in her original request for therapy, but she has also radically reorganized her perception and understanding of them. She has effectively dealt with a psychological trauma that was at the source of her memory problem, and has even resolved some of the early childhood experiences that gave her, in part, a predisposition to this trauma. Instead of being bitter at her young doctor, she can now understand him as a victim of his own limited education. She certainly has an enhanced sense of the worth of her own perceptions, feelings, and thoughts and a profound respect for her own unconscious processes.

CHAPTER 8

Case 11 Emotional Coping

Resolving Affect and Phobia with New Frames of Reference

Part One: Displacing a Phobic Symptom

Mrs. A was a highly intelligent, attractive computer programmer, recently married, who requested therapy for an airplane phobia. She reported that she had been in a minor airplane accident involving a landing that shook her up a bit. The fright from this experience quickly generalized to any form of air turbulence or vibration when a plane was in the air. She was able to enter an airplane and even taxi along the runway with no fear. Her phobia" actually began the moment the plane lifted off the runway. She was in great distress while airborne, but was comfortable again as soon as the plane touched ground.

She was eager to experience hypnosis and proved to be a very responsive subject. Because of this the senior author felt he could request a strong commitment from Mrs. A in her very first therapy session.

Commitment on a Conscious and Unconscious Level

E: I requested an absolute commitment from Mrs. A that she must agree to do anything I asked. I made her verbalize a promise to do anything I asked - *good or bad, the worst or the best.* You are a woman and I am a man. Even though I'm confined to a wheelchair, we are of the opposite sex. If.you only knew how grudgingly she gave that promise; she did not enjoy giving it, but she gave it. She thought about it for seven or eight minutes and finally said, no matter what you do to me, it couldn't be worse than that awful fear. Then I put her in a trance and went through the whole thing again until I got the same promise when she was in a trance.

R: Why did you have to get the same commitment while awake and in trance?

E: Unconsciously you don't have to do what you consciously say you will. In everyday life, you may accept an invitation for dinner, and later your unconscious lets you forget it.

R: So this is an example of a mental mechanism in everyday life that can interfere with therapy unless you make provision for it as you do here. You aroused quite an emotional storm in her; she was really affected by your demand for an absolute obedience, which is rather unusual in modern psychotherapy.

E: Yes. It took an awful lot of courage on her part. Now why did I ask that kind of promise? She said she had an airplane phobia, but I knew she didn't because it was only when the plane was in the air and she had no control over anything that she had fear. As long as the plane was on the ground, there existed a possibility of getting out. But up in the air she was in a state of absolute commitment.

R: So her problem was in giving a commitment?

E: Yes, and I made her give, a commitment, a total commitment. The thing is, you couldn't do therapy with her except with the actual problem present. You can't remove a wart unless the patient brings the wart into the therapy room.

R: That's the dynamics of the situation; you had her reify her fears and bring them into the therapy session.

E: That's right, made her fears a reality I could work on, a reality I could then put in that chair she was sitting in and leave there.

R: By making her give you a total commitment, you brought her fear of total commitment into the therapy situation. By hinting about sex between you, the therapy situation became as fearful as her phobia.

E: That's right, there was a body threat in both. I had to make it so that it might all turn out terrible. I could not get a commitment by just asking her to imagine herself in a locked room. It had to be *this room,* something that would be truly horrible.

R: She might have been stuck with a dirty old man.

E: That's right.

R: You have guts to pull off these things.

E: She had to have her psychological problem with her at the time that I treated her. She then went into a trance quite easily. She was actually commited to do anything. She had no freedom of any kind. She was in a state of total commitment. Once in the trance state I had her board a plane and ride through a storm in her imagination. It was sickening to see; she actually went through a kind of convulsion. It was horrible to watch.

Concrete Displacement of a Symptom Outward

E: I let her go through that plane trip with great air turbulence, and then I told her that she would soon feel comfortable and at ease. She would then suddenly find that all her fears had slid off her onto the chair she was sitting on. She was then awakened. She immediately leaped out of that chair! I called in my wife and told her to sit in the chair. As she started to the patient yelled, No, no, don't! and physically prevented my wife from sitting.

R: You were testing the patient?

E: No, I gave her an opportunity to validate that the chair contained the fears.

R: I see! It was actually a way of helping her recognize and ratify her own therapeutic response of concretely displacing her fears onto the chair.

Posthypnotic Suggestion with Supportive Cues

E: I then gave her a direct posthypnotic suggestion that she was to actually take a plane trip in reality to Dallas. She had given me her absolute promise. I then told her it wouldn't be necessary to see her again until after she returned from Dallas. You'll take a plane from the Phoenix airport. Of course, you'll have some question about it. When you get back to Phoenix from Dallas, you will have discovered how beautiful it is to ride a plane. You will really enjoy it. When you reach Phoenix airport on your return, call me up and tell me how you enjoyed it.

Before terminating that trance, I gave her other posthypnotic suggestions as follows: You have lost your phobia for planes. In fact, all your fears and anxieties and horror are sitting in that chair where you are sitting. It's up to you to decide how long you want to sit there with those fears. You should have seen how she jumped out of that chair!

R: That's how you awakened her. You displaced all her fears onto the chair. That's why she suddenly jumped out of the chair. Such an immediate and vivid response was also the kind of feedback you needed, to know that she would follow your other posthypnotic suggestion to actually take a plane to Dallas.

E: I then wondered what I should do to be sure of the effectiveness of that single trance. I had my daughter take three pictures of that chair - one picture overexposed, one that was underexposed, and one that was normally exposed. I labeled the one that was underexposed, Where your phobia and troubles rest and are dissipating into nothingness. The overexposed photo, where only the outline of the chair was darkly visible, I labeled, Where your problems are sinking into the gloom of total doom. The normal exposure was labeled The permanent resting place of your problem. I sent her those photos each in separate envelopes. They are her St. Christopher's medal.

R: You mean she carries them with her when she goes on a plane?

E: Yes. I don't care how educated people are, they still believe in good-luck pieces. Those photographs were her good-luck pieces; it's a part of everyday living.

R: Those photographs were supportive cues that she could take out of the therapy situation to reinforce the posthypnotic suggestion. Posthypnotic suggestion does not necessarily function because an idea is deeply imprinted in the mind during trance. Rather, posthypnotic suggestions are always in dynamic process and as such require outer and inner stimuli and cues to evoke and reinforce them. That's why it's so useful to associate posthypnotic suggestions with some inevitable patterned behavior the patient will experience after trance.

E: She followed those posthypnotic suggestions, and when she returned and called me, she said in an ebullient tone of voice, It was utterly fantastic. The cloud bed below looked so beautiful I wished I had a camera. Months later, when she had occasion to return to the same room, it was ridiculous how she avoided that chair and prevented others from sitting in it.

Part Two: Resolving an Early-Life Trauma at the Source of a Phobia

The senior author developed a number of useful approaches to dealing with emotional trauma and facilitating an appropriate balance between intellectual and emotional experiencing. The most basic of these appears to be a separate experience of each before their final integration.

R: How and why do you separate the emotional and intellectual aspects of a life experience as a therapeutic approach?

E: You separate the emotional and intellectual content because so often people cannot face the meaningfulness of an experience. People cry and do not know why they cry, they feel suddenly elated and know not why. In using regression therapeutically you first recover the emotions in trance to help the patient recognize them. Then put the patient back in a trance; this time leave the emotions buried and let the intellectual content be recognized. Then put them back in a trance a third time and put the cognitive and emotional aspects together and then have them come out of trance with a complete memory.

R: You have them experience emotions and intellect separately and then put them together to integrate the now totally recovered memory.

Separating Emotion and Intellect

To illustrate this approach the authors decided to call upon Mrs. A, whose airplane phobia was discussed in Part One. While the senior author's unusual means of dissociating and displacing her fears had indeed apparently resolved her phobia (it was now two years after the therapy), it was felt that a more adequate resolution could be achieved by helping her develop greater understanding of herself. Mrs. A readily agreed to the idea of further hypnotic work because she was very interested in the experience and was willing to permit tape-recording and a number of observers. As the group assembled in Erickson's office a very friendly and positively optimistic mood was generated as we were all introduced and a few stories were told about how Erickson had helped one or another of us with hypnosis. *Rapport, response attentiveness,* and an interesting *therapeutic frame of reference* were thus facilitated in Mrs. A as she basked in the light of high therapeutic *expectation,* This was an illustration of how Erickson likes to use an audience to generate a therapeutic milieu. A hush gradually fell over the room as all of our attention was directed toward her. Erickson begins with the counting induction with which he had previously trained Mrs. A.

Trance Induction and Facilitating Posthypnotic Suggestion

E: One, five, ten, fifteen, twenty!

[Pause]

Very deeply in trance.

[Pause as Mrs. A closes her eyes and becomes quietly immobile with a relaxed face. She evidently has entered a deep trance very quickly.]

E: Now A, after you awaken I will ask you
casually,
Are you awake?
In a moment you will say yes,
and as you say yes,
there will come over you
all the horrible feeling that you experienced

Sometime
before the age often,
feelings about something
that you can talk about
to strangers,
but
you'll have just the feelings.
You won't know what the thing is
that caused those feelings.
You will just feel feelings,
and you won't know what is making you
feel so miserable.
And you will tell us
how miserable you feel.

[Pause]

Get a firm grip on those horrible feelings.
You won't know about them until after
I ask if you are awake
and you say, yes,
and at that moment those feelings will hit you hard.
Do you understand now?

A: Um hum.

E: All right, twenty, fifteen, ten, nine, eight, seven, six, five, four, three, two, one.

R: This is a basic approach for facilitating posthypnotic suggestion. You request a simple

response like the answer yes that is almost inevitable in response to your question, Are you awake? You then associate that very easy response with another, vastly more complex and difficult posthypnotic suggestion to reexperience horrible feelings before the age of ten without any awareness of the cause of the feelings. You are facilitating the reliving of an old emotion by dissociating it from an awareness of the cause of the emotion. The easy yes response tends to initiate an acceptance set (Erickson, Rossi, and Rossi 1976) for carrying out the more difficult posthypnotic suggestion that is to follow. If you had noticed that a particular patient tended to nod her head yes in everyday life, you would *utilize* that head nodding as a vehicle to facilitate the more difficult posthypnotic suggestion. By requesting responses that are already high in a patient's response hierarchy, it is more likely that you will be successful in facilitating an initial post-hypnotic response, and most importantly, you thereby initiate an acceptance set for the more difficult posthypnotic suggestions associated with it.

E: Yes, that's a beautiful wording. Notice I emphasize that she is to get a firm grip on those feelings. Then when I count down I skip from twenty to fifteen to ten, but then give an impressive countdown from ten to one by single digits as she gets a grip on the feelings that are to emerge.

Trance Reinduction When Carrying Out Posthypnotic Suggestions

A: Oh, I like it. It is so restful. I didn't want you to count.

E: Are you awake now?

A: Yes.

[Mrs. A looks a bit startled and becomes quietly self-preoccupied for a moment or two. Her face frowns, and she obviously begins to experience some internal stress.]

R: Her slight startle and quiet self-preoccupation are actually indications of the momentary development of another trance as she begins to carry out the posthypnotic suggestion (Erickson and Erickson, 1941). Although talking and acting as if she were awake, she is probably in what you define as a somnambulistic state as she experiences the fearful emotions recorded in the next section.

Emotional Experience Without Intellectual Insight

E: What's the matter, A?

A: I don't know, I don't want to look. There is something I don't want to see.
I don't know what, but I don't know what to tell you.

E: Talk about your feeling. Tell me what you are feeling.

A: No, I'm afraid. There is something there that I don't want to see, and I don't want to look. I'm afraid of what it is, and if I look . . I don't want to look.

E: You don't need to look. Just talk to me about it.

A: It is just fear. I, I want to forget. It will go away if I don't look, OK?

E: I don't think the feelings will go away.

A: Yeah, because . . . because I'm just afraid. There is something I... I don't know what to tell you about it, but I am afraid, I'm afraid.

R: Mrs. A is genuinely frightened and only apparently awake following your posthypnotic suggestion to experience a horrible feeling without knowing why she is experiencing it. You have thus accomplished the initial part of this hypnotherapeutic approach by having her first experience these feelings separate from their source and intellectual content. You now release her by counting to twenty again to reestablish a comfortable state of trance.

Reinducing Trance Comfort With Posthypnotic Suggestion for Intellectual Insight: Protecting Patients in Trance: A Feeling Approach

E: One, five, ten, fifteen, twenty.
Now you feel comfortable.

[Pause]

And you will again,
now,
can't you?

A: I'm beginning to.

E: That's right.

[Pause]

Now the next time I awaken you, A, I have a different kind of task for you.
When next I ask you casually if you are awake,
you will say 'yes,'
and then
there will come to your mind
something that could have scared you
years ago.
But you won't feel any emotions at all,
is that all right?
It won't scare you, is that all right?

A: I will remember, but I won't be afraid?

E: You'll just remember, Yes, when I was a little kid I was scared. That's the way you'll remember it. You will be able to laugh about it and take an adult person's view. I'll be cautious,
A,
to make certain
whether or not you should
identify it,
OK?

A: All right.

E: I ask for her approval to view the past when I ask, Is that all right? I describe what she is to do and get her agreement. Each pause in my final sentence is an independent message saying that I will protect her. Each part is a separate reassurance.

R: Each phrase is a reassuring suggestion in itself within the overall sentence about being cautious for her sake.

R: After her previous experience of an uncomfortable emotion Mrs. A is rather hesitant about going on. It's therefore important that you reassure her by letting her know she will be able to laugh at it from an adult person's point of view. Most patients are vulnerable in trance; they need the therapist's protection. Therefore you let her know that you will be cautious and make certain it will be OK for her to identify her experience. If it was about to become traumatic, or not the sort of material she could share with strangers, for example, you could easily shut it off by distracting her, telling her to stop, or giving her the counting signal to reenter trance.

E: My approach is very casual even with this difficult material, and that makes it easier for her. It's hard to say no to a casual easygoing approach.

R: This illustrates how you often work on a feeling level: Intellectually a person might want to say no, but that seems ridiculous on a feeling level where you are so casual, warm, and permissive. It feels wrong to say no!

Trance Awakening with Intellectual Insight: The Transformation of Painful Affect: A Genuine Age Regression with Adult Perspective

E: Twenty, fifteen, ten, five, four, three, two, one.
Not a restful trance.

A: Not as restful as before.

E: No?

A: No. I, I feel an apprehension. I don't know why, and I don't know what is causing it, but I feel apprehensive.

E: Want to ask Dr. Rossi? Are you awake yet?

A: Yes.

[Pause as Mrs. A looks a bit puzzled. She is again apparently experiencing a momentary trance as she begins to carry out the posthypnotic suggestion for recall without emotions]

E: Would it be all right to tell us?

A: What is in my mind is a void. It is, um, a void, I don't know how to describe it, but it is like looking at, un . . .
Oh. . . yes! Fantastic! I know what it is! Shall I describe the scene to you?

E: Oh, yes!

A: Oh, yes, it is a bridge. Do you remember when I told you before I was afraid of bridges? The scene is coming up a bridge . . . as you come up you see nothing of reference, but a void. The car or whatever I am in, and it must be a car, I'm sitting in it in such a way that I see nothing. I don't see the superstructure of a bridge if there is any, or the hood of a car. I am looking out and see nothing all of a sudden. Where I was looking at before and seeing - trees or grass or something, pasture, that I can relate to. All of a sudden there is a void and I see nothing to give reference. And it is a bridge. I know where the bridge is. I am aware of where this bridge is. I can't relate to how old I am or whom I am with or anything like that. But, yeah, OK.

E: Tell me something about the bridge.

A: Where is it? Well, it is on the way to my grandparents in northern California. And it is a bridge that has a very steep incline so that as you are driving up, you then reach the top and you break over so that as you are going up, you are not aware of anything, there isn't anything. You can't see anything to relate to unless you are looking out at the side, but if you are looking straight ahead, there is nothing until you break over onto the top of the bridge.

E: How soon do you think you will discover your age?

A: I don't know because I have gone on that bridge many, many times as a child.
Eight comes into my mind, but I don't know why eight. Because I could have been any age, going over the bridge so many times, not just one time.

E: Is that sufficient, Ernie [R]?

R: Yes, I think so.

R: Whereas before she was greatly distressed with the emotional component of the experience, she now appears to be fascinated and even a bit elated (Fantastic!) when she recalls the scene

with intellectual insight. Affect is thus not completely eliminated in this second phase, when you supposedly have the patient discover the intellectual component of the experience alone. Ail negative affect has certainly been dissociated from the memory, however, and she does indeed experience it with an adult person's view, as you suggested. The fear and anxiety she experienced as a child have been replaced by the curiosity and fascination she can feel about the experience as an adult.

E: In my previous session with her I said the view from a plane would be fantastic, and she uses that word here.

R: This suggests that there is a transformative aspect in her hypnotic work that is restructuring a previously painful affect into a new frame of reference where it can be experienced as fantastic!

E: When she speaks of car ... I am in ... I'm sitting in it in such a way that I see nothing ... it is in the present tense, which indicates she is really there.

R: That aspect was a genuine age regression in which she was actually reliving an early life experience rather than simply remembering it.

E: Then I ask her to tell me about the bridge, and she experiences a transformation of the trauma into a more adult recollection. First she was an adult being a child reliving a past experience, then she is an adult and understands it. She is in two identities simultaneously; child and adult are working together, becoming integrated.

Trance Reinduction and Comfort

E: One, five, ten, fifteen, twenty.
Now you have done beautiful work so far today, A. Very good work. Now

this time
I am going to awaken you, and I want you to feel really comfortable, very
rested, very relaxed,
feeling as if you had eight hours of rest.
You will be surprised when you look at the clock and notice the time.
And again I'll ask if you are awake.
Immediately after
You will say yes.

R: You now prepare her for the final task of integrating the emotional and intellectual aspects of the experience by suggesting that she will first feel comfortable and relaxed as if she's had eight hours of rest. This is another example of giving an easy and much desired posthypnotic suggestion to initiate an acceptance set for the more difficult posthypnotic suggestion you will associate with it. It's also a way of rewarding and reinforcing her for the work she's already done when you tell her she's done beautiful work so far today, A. Very good work.

E: Suggesting eight hours of rest also utilizes what we experience in everyday life: You frequently sleep on something in order to deal with it.

Posthypnotic Suggestion for Integrating Emotions and Intellect, Child and Adult

E: The entire episode will flash in your mind
with utter ...
with utter and complete vividness.
Now did you understand my words, A?

[Pause]

A: Um?

E: Your first look at the clock.
You'll probably be astonished that it is not later,
a lot later,
than this.
You can feel so rested. Tell how rested and comfortable you feel, how much
you enjoyed this trance state.
And then I ask you
if you are awake,
and you will say yes,
then immediately
this entire episode
will flash
into your mind very vividly.
Is that all right?

[Pause]

A: Um. Last time
you said complete.
You said complete and vividly.

E: That's right.
Completely,
intellectually and emotionally
complete.
So that you will know what your feelings *were then*
and
everything about how you felt *then*,
even knowing yourself then.

A: I'm confused.

E: It is perfectly all right, A.

A: I will know my feelings, or I will feel my feelings?

E: You will *recall* your feelings. [Pause]

E: Just as long ago and barefoot on the first day of spring, I felt so good to be barefoot, I jumped and landed on some broken glass. I can recall my agonized shriek of pain and my bitter feeling of disappointment that it would be a week before I could go barefoot again. But I can be amused by that now. It did hurt and I recall how it hurt. I can feel it in my heel right now, my right heel.
I can laugh about it, and that bitter feeling disappears. I can go barefoot tomorrow and I just persuaded my mother to let me go barefoot that evening.
I can be amused by it now. You will recall your episode, you can describe it fully and describe the feelings you had then. Now do you understand?

A: Um hum.

R: You're now making an effort to help her integrate emotions and intellect, child and adult. Why do you resort to giving her a personal example of what you mean?

E: I can always *show* you what I mean rather than explain it. Can you describe a fishy handshake?

R: I wonder, too, if such concrete, imagistic illustrations make better contact with the right hemisphere, where such personality integrations may be taking place (Rossi, 1977). Such concrete illustrations also evoke ideodynamic processes much more readily than abstract and intellectual formulations. From this point of view it can be regarded as multiple-level communication.

Integrating Emotional and Intellectual Experience from an Adult's Perspective: Reassociating and Reorganizing Inner Experience

E: All right.
Twenty, fifteen, ten, five, four, three, two, one.
Feeling comfortable?

A: Um?

E: Feeling comfortable?

A: I feel like I am waking up.

E: How much do you feel you have slept?

A: I feel like I have been asleep for a long time. Like it is time to get up. Oh, dear!

E: Are you awake now?

A: Yes. Um. Um.

[Pause as Mrs. A appears lost in thought. She is again apparently experiencing a momentary trance as she begins to carry out the posthypno-tic suggestion.]

E: What are those um's about? Tell it fast.

A: Oh, there are so many things to tell! It is a cloudy day and I am in a car with my parents and my sister. I don't know where my brother is. I'm wearing, I can't think of what I am wearing. I'm wearing a cotton pinaforelike dress, but I don't understand why I am wearing that dress when it is so cloudy outside. We were going to my grandmother's and my grandfather's and it is, how did I know it was Sunday? It's Sunday, how could I tell?

I guess because my father is not working, but he does work on Saturdays, but it is Sunday. It is Sunday afternoon. We are going over to my grandmother's and grandfather's and my grandmother has promised me chicken noodle soup for lunch. And we are in a blue car. I wonder if my parents had a blue car? They must have. This is like a newsreel in my mind. Events are happening in my mind.

We are driving down the road, and it's the Sacramento River Bridge. My mother is unhappy about something, and she asked me to sit back in the seat. I don't know why, maybe Diane and I were playing. I'm sitting back in the seat and I'm looking out straight ahead. No, I had gotten up again and am holding onto the back of the seat, looking out the front window, and we are driving and there is nothing.

And I close my eyes because I couldn't see anything, I wasn't aware of anything to relate to. I was aware of bouncing over and knowing that if we made the next bump I'd see something. And that's all.

It's like a newsreel in my mind. If I just wait long enough, some more will happen. I opened my eyes when we went over the second bump.

E: How old are you?

A: I seem to be eight. For some reason eight comes into my mind. I feel eight but I can't be eight, but the dress that I am wearing would be a dress that I would wear at that age, I think. But I don't see my brother. I don't know where my brother is. If I am eight, my brother should be five, but I don't know where my brother is, but my sister is there.

Eight comes to my mind, but I can't tell you why. Maybe because I said it earlier, that I felt eight, but I don't know why. There is no fear, though. I am not afraid of anything.

E: How was it?

R: It seems very fine.

A: How was what?

R: Your work in dealing with these experiences.

A: It's not frightening anymore.
There isn't the fear.

E: Now it will be all right for you to remember the fear.
You just showed it to us a few minutes ago.

A: Oh, it seems very innocent now. There is nothing that I am afraid of.

E: A few minutes ago, how did you feel?

A: Why was I afraid? Now I'm not, it doesn't frighten me in the least. It was just an incident as a child.
I was afraid, though, I remember, and that's why I was very afraid.

E: What happened to her fear?

R: I wish I knew.

R: Integrating the emotional and intellectual aspects of the experience from an adult's perspective now enables her to relive the experience without the child's fear. This is an emotionally corrective approach that helps the patient reas-sociate and reorganize her inner experience in a therapeutic manner. Once a certain amount of catharsis of the traumatic aspects of the experience takes place (in the first phase of the reexperiencing the emotions without the intellectual component), the entire experience can be integrated and worked through from a new adult perspective in another relatively brief trance. It's interesting that under this third trance condition, where she is to reexperience both the emotional and intellectual aspects of the experience, she recalls much more detail than with either alone. That this is something more than a simple recall of a lost memory is indicated by the fact that she reports it as a newsreel in my mind, wherein it seemed to come to her autonomously as an unconscious process unfolding itself spontaneously, rather than a labored effort of the conscious mind to remember.

E: She was able to restructure her early life experience to remove the pain associated with it. Even though she did restructure this early life experience, you can always, again, separate that life experience into its emotional and intellectual components and have her reexperience the child's painful emotion.

R: What do you feel is actually involved when you speak of restructuring a life experience? Do we simply give it new associative connections so it is not isolated in a pathogenic manner? What is

restructured?

E: [The senior author gives the example of a patient overcoming his fear of swimming. The patient reported that if he just wades halfway into the water, as he used to, he can feel the old fear somewhat within. When he takes his new position and swims, however, the old fear disappears. A potential for the old fear remains, but new activities can generate emotions that can replace or restructure it in modifications of the old situation.]

R: In restructuring an old life experience we are developing new associative pathways, facilitating new responses to the old fear-provoking life situation. The old memories and pathways are still there. They will always be there.

E: We are giving the patient new possibilities and we are taking away the undesirable qualities. Usually it's best to have patients experience the emotion first and later the intellectual, because after they have experienced the emotions so strongly, they have a need to get the intellectual side of it.

R: I see, this dissociative approach enables emotion to surface more easily and then strongly motivates them to get the intellectual. Do you have any other means of dissociating experience other than this separation of emotions and intellect?

E: Yes. You can have the patient recall one single facet of the emotional experience - then an unrelated intellectual facet, like a jigsaw puzzle. The entire experience can be recovered, the whole meaning can be put together, only when the last piece is put into place.

Part Three: Facilitating Learning: Developing New Frames of Reference

After a leisurely discussion of the foregoing events by the group Mrs. A described some of her current problems with a course of academic study that made great demands upon her time. The senior author now decides to utilize her motivation for more efficient study habits to facilitate her learning processes. He induces hypnosis in his usual fashion with her and continues.

The Utilization Approach

E: The alterations I'm going to suggest, the first is this:
homework is tedious, tiring, exhausting. I think
homework
carries with it
a sense of something
well done, well accomplished,
and the feeling
it is going to be done,
is being done,

and has been completed will carry with it
a very partial feeling
that will enable you to
concentrate better,
learn more rapidly,
and enjoy the entire process.

[Mrs. A nods her head yes in the rapid, abbreviated manner that is characteristic of a conscious intentional process]

You think it over,
don't nod or shake your head yet,
think it over.

E: You don't want the patient to agree with you too soon. It's nice to think it over before you buy a house.

R: As is highly characteristic of your style, you begin by first accepting her own frame of reference, homework is tedious. This opens an acceptance set. You then add your initial suggestion, homework carries with it a sense of something well done." Your suggestion is a truism - anyone would have to agree with it - and that further establishes the acceptance set. To this you finally add the easy-to-accept suggestion, a very *partial* feeling that will enable you to concentrate better, learn more rapidly, and enjoy the entire process. You don't directly command her, you simply state truisms about better learning and associate them with her own inner experience in such a way that she cannot deny them. She accepts them as valid for her own experience and thus she receives and accepts your suggestions. You do not add anything new with these suggestions . Rather you evoke and utilize her own real-life experience; anyone who has ever, at any time, done their homework (or any other kind of learning) usually has had a feeling of accomplishment, and this is invariably associated with a very partial feeling that they can learn even better some time or other. Your suggestions about better concentration and more rapid learning thus reinforce aspects of her own experience which you have evoked. You (1) establish an *acceptance set* and then (2) *evoke* aspects of her life experience that you can then (3) *utilize* to help resolve her current problem. This is a typical example of your utilization approach to therapeutic suggestion. She accepts this so quickly with a nodding of her head that you must tell her to think it over. You want to let her unconscious have enough time for a thorough search of the relevant inner processes that can implement these suggestions.

E: I let her have a little taste of a good thing with a very *partial* feeling, so she will soon tell herself that she wants the whole thing. It's a common life experience to take a taste and then want the whole thing. A mother says, Just take a little bite. But our patient didn't even hear me say, Just take a little bite."

Generalizing a Learning Frame of Reference to Restructure a Phobic Problem

E: The other alteration is

this question of flying.
The initial apprehension
that can be
transformed possibly
into
a sense
of the task,
the responsibility
of doing the task.
One can always be apprehensive
about a task.
You always know that you can fail,
then you are hooked
and realize
you've done this sort of thing before. You have enjoyed it before and you can actually enjoy starting out on new assignments. Instead of boredom there is a time
when you enjoy being within your body,
a feeling of resting,
feeling of comfort
while your mind's eye
is exploring
the things that really give you pleasure.

[Pause]

R: You now generalize the learning frame of reference you've just developed to help restructure her understanding of her fear of flying which you helped her with some time ago. This is something of a surprise; she could not have known you were going to bring up this old problem again for a new and more adequate resolution.

E: Yes, I'm now transforming the phobia problem by placing it into a frame of reference of dealing with intellectual tasks, where she is really an expert.

R: Although she's asking for help as a student, she is, relatively speaking, an expert in solving intellectual tasks.

E: She has a very strong desire to do good work. She is strong there, so I'm using that motivation to deal with the place where she is weak-her airplane phobia.

Illustrating Open and Flexible Frames of Reference

E: I know flying to France
at night,
the plane was crowded
I was physically rather uncomfortable at the time.

I knew we'd arrive in France at breakfasttime,
and we'd barely get our dinner eaten
before we were handed our breakfast.
But throughout that flight
I kept thinking about
my boyhood concepts
of what the ocean was.
Its unlimited span,
and how that contrasts
with my current understanding.
I thought about all of my daydreams as a boy
and how they had evolved.

[Pause]

R: You now introduce a pair of illustrations about how one can maintain open and flexible frames of reference to become more adaptable to unusual life contingencies. The second illustration from your boyhood has particular relevance for her because your conception of an unlimited span of the ocean corresponds with her early fear of the void over the bridge. You are attempting to help her restructure some of her early fearful childhood associations to void with a more adult perspective.

Associating Therapeutic Themes

E: In going back to the first change,
a sense of accomplishing something,
of knowing that you have a good job to do,
that you are doing a good job,
that you are reaching in,
that you have concluded with a joyful sense of accomplishment.

R: You now return to the problem of academic learning. By associating this academic problem with the phobia problem you are implying that they can both be resolved by the same process of learning to adopt and maintain more open and adaptable frames of reference.

Restructuring Sensory Experience: Translating Therapist's Words into the Patient's

E: A farmer knows he has done a good day's work because his back is
comfortably very tired.
And so you can accomplish homework
with profound feeling of accomplishment
and the knowledge that you can go to sleep and sleep soundly,
your homework is done,
and that the overall picture
of your homework is

a good thing and also a good thing to have in the past,
and the nice feeling comes during the process.
So that
the whole is worthwhile and
is not going to distress you.
Is that all right?
And now the transformation,
the alteration that I have suggested
in regard to flying I have suggested one
way.
But I expect you to translate everything I have said,
both connections,
into your words,
your phrases,
so that the alterations
are set in your terms,
not mine.
And I don't need to know those.
You do.

[Pause]

E: What does comfortably very tired mean?

R: The farmer's tired back is his cue that he can be comfortable knowing he's done a good day's work.

E: The mind restructures the tired feeling into a comfortable feeling. You don't have to have a Ph.D to do it!

R: You end this section with an important suggestion wherein you encourage your patient to translate your words into her own. Your suggestions are therefore received in an open-ended manner that allows the patient's own individuality to utilize them in an optimal and personal way.

Patient Feedback and Further Therapeutic Illustrations

E: I have a
former alcoholic as a patient.
Last time
he saw me
he said, Let's go out and have a good drink.
The wife and I went with him to have a good drink.
We had daiquiris and he had a glass of milk.
Now all three of us had a good drink.
Now I was suggesting

a very nice feeling
for you
in your definition
of a nice feeling
in two regards:
homework
and travel
Relaxed? All right.

A: Um hum. In the case of homework the end result is what you say, it becomes a sense of accomplishment and pleasure. It is the process of after a hard day of concentrating on a lecture, that it takes a lot of concentration and discipline to sit and then study another three or four hours at night. After being tired all day, the only thing that pushes me to do that is the fact that I know that I will be happy when it is done and will feel better. And when it's done I will sleep better. So those are the reasons for doing it. The problem is not realizing the end result. I do realize what I want the end result to be, which it is. The problem is the concentration and the discipline necessary to do that.

E: All right, now I'll explain further.
I worked out this plan.
I borrowed six novels from the library.
I grew up in a home where there weren't many books and I knew
my knowledge of literature was very poor,
and so I would sit down and read fifty pages of one novel,
study hard in chemistry
for twenty minutes,
shift into another set of gears and study
physics for twenty minutes,
and another fifteen minutes on my English assignment,
read part of the next novel,
and keep going around
from novel to textbook,
perhaps another novel,
another textbook, all shifting gears.
Because every time you shift from one pattern of physical activity, you rest from the previous activity.
On the farm I learned to pitch hay right-handedly and left-handedly.
When my right arm got tired, I rested it by using my left hand.
In chopping wood - right- and left-handed. Always resting first one arm and then the other.
Alternating in hoeing in the garden, I did the same thing.
In studying
chemistry,
it is so different than reading a novel.
Reading a novel is one kind of an exercise, and a chapter from a psychology book is another kind of exercise,
so I was always working at top speed at each of the things that I was doing and resting

from all the other things.
Now working all day tires you. Studying your homework at night is also tiring.
But
to untense that part of your body fatigued by the day's work
and work with the rest of you on homework.
Listening to lectures is one thing,
doing paid work is another thing,
and studying is a third type
of exercise.
You alternate them and understand that you can rest
the lecture-receiving apparatus
while you're doing homework,
and rest from homework activity when you are doing office work.
Because it all requires different sets of patterns of functioning.
Do you understand?

A: Um hum.

E: Now you can elaborate that in your own understanding?
When a friend entered medical school,
she heard lectures from eight in the morning until five at night. And then from six to eleven she was in the laboratory.
It took her a while to discover that she could use different parts of herself for the lectures in the day and different parts of herself in the laboratory at night. When she got back to her room she rested all of herself.

She has been rather startled to see how neatly and precisely she can divide herself up in accordance with her needs. And she has added to that crocheting shawls and baby blankets and afghans. It is so restful when she is starting to crochet an afghan. And the joy of crocheting an afghan for her sister in Ethiopia really soaks up the fatigue of studying.
In a very delightful way of doing it,
in a careful
unconscious thinking it out,
you can devise
a mastery of your own functions

so that you can
work out patterns
of function.
Do you think you understand me now?

A: Yes.

E: You can think about those things at your own convenience. You can decide whether or not to accept these alterations.
I think they are good,

perhaps you can find them good.
But it's your advantage,
your comfort
in your ease in studying
and hearing lectures,
in understanding homework
that I really
want to promote.
And I want
your work
while you're overseas mentally
to carry with it something enjoyable,
overtones and undertones.
Over hills to grandmother's place
is very nice,
appealing,
to everybody. ,
Then jingle bells
all the way,
overtones and undertones.
I don't know what your acquaintance is with
sleighs and jingle bells,
you undoubtedly know the song,
There are so many things that have
overtones, undertones of enjoyment.
I can think of how much easier it was to churn butter
for my grandmother than it was to do it at home.
Same job
but in a different setting.
Any question, A?

A: Not really, I'm fine.

E: Now
because what you can do can be your own
in some future time, you might like to talk about it.

R: In this section Mrs. A gives you some valuable feedback on how she is receiving your suggestions, so you are able to adjust your orientation to fit her needs more exactly. You give her more illustrations of how to facilitate her own learning processes and continually offer your suggestions in an open-ended manner so that she has to do continual inner work in organizing your words into her own terms. This is a state of very active trance learning. She is not at all passive. There is an intense rapport between you; it's almost as if there was a kind of direct mind transfer between you.

Confusion and New Learning

A: I'm having trouble.
I understand about studying and homework, and that makes sense to me, but I'm confused about flying
and about what you said earlier about doing the tasks that I face.

E: It's okay, A.
Recognizing that the task ahead of you
has sufficient proportions
to mean a great deal.
You look at your work the way a surgeon looks at an operation.
It is a simple appendectomy, but if you are a good surgeon,
you know
that in the United States,
quite unexpectedly,
a certain number of simple appendectomies die
from surgery.
Therefore,
you know there isn't such a thing as a simple appendectomy.
So you set about
making it
a simple appendectomy.
Taking care to omit
nothing that is important.
And have the good feeling this
is going to be a simple appendectomy because you are doing it.
A very good surgeon feels
just a simple operation and it is going to turn out right because
he is not going to omit anything and he is going to enjoy doing it
and the patient is going to enjoy having had it done.
You give the proper amount of respect
to the task in hand,
realizing
that there are hazards in any human performance,
which have to be met
by each functioning human being,
and then
the enjoyment
of looking forward to doing it, a simple act of appendectomy tomorrow,
looking forward to enjoying that flight tomorrow,
looking forward to the enjoyment of preparing
whatever it is.
And letting that take over boredom.
Boredom narrows your vision

and restricts the freedom of your mind to think.

A: How about enjoying anticipation of bad weather?

E: There is nothing more pleasant
than the sound of raindrops on the roof
when you are lying on the hay in the barn,
knowing at least you won't be out in the hot sun pitching hay.
And knowing that you have a few good meals under your belt
before you get out in the field,
and then the rain.
Most bad weather for the farmer is
in regard to cutting hay.
Well, it certainly isn't a blizzard.
If it were a blizzard,
a blizzard is terrible
in so many different ways.
And bad weather,
30,000, 35,000 feet up is
a different kind of weather than at
zero feet.
I often wonder,
when I was at 30,000 feet above sea level,
what would it be like if
I could sense
how a plane was dealing with that air
at that speed.

A: I do, I do that. I do two things that you suggested. I try to think of and enjoy the clear air turbulence that wasn't expected. I try to think of all the feelings of whether it was a roller coaster feeling or a bumpy car feeling. What kind of feeling it was.

R: In this section Mrs. A clearly illustrates the utilization of trance as a state of active learning. She is confused about how to generalize her acceptance of a more adequate approach to academic learning to her phobia for flying. Her confusion, of course, is itself proof that she is in the process of giving up an old, less adequate frame of reference for a new one that she does not yet understand. You now take advantage of this situation to facilitate more openness in her frames of reference in the following sections.

Depotentiating Habitual Mental Sets: Facilitating Flexible Frames of Reference

E: But you had no frame of reference.

A: Then I try to think about what was happening to the aircraft in terms of structural

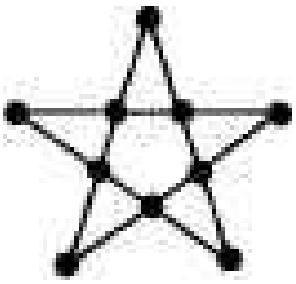
stress and knowing that the structural specifications allowed for stress of this magnitude. But I was uncomfortable and quite relieved when it was all over.

E: All right, I will give you an example
that shows what I have done for you before.
Could you plant ten trees in five straight rows with four trees in each row?

A: Ten trees in five straight rows, four trees in each row?

[Pause]

[After a number of futile attempts, the senior author shows her the following star-shaped diagram as a solution to the problem.]



A: Oh, I didn't think that. I was trying to relate it to air turbulence.

E: You can't understand air turbulence, can you?
You can't understand it in terms of air turbulence on the ground.

A: I can understand it intellectually in terms of what happens atmospherically. How it forms and how it affects bodies and that sort of thing. I can't understand my response emotionally.

E: All right, and how can you understand
you have two responses; intellectual and emotional?

A: Oh, yes, that's for sure.

E: Now sometimes you can have intellectual knowledge of it, and you may be emotionally behind it.

A: I can't separate the emotional in this case. Intellectually I can understand a lot of things that I fear - in this case air turbulence. But a lot of fear as it was before, is an uncomfortableness.

E: Now that puzzle there,
five straight rows,
four trees in each row,

only ten trees. What you did was you dragged into my presentation the definition of a row, and a straight line, a second row.

A: Yes, I did.

E: It would be nice if this puzzle could be a way of treating air turbulence because you can only understand it in certain frames of reference.

A: I'm not relating this to air turbulence. I understand intellectually air turbulance.

[Here Erickson distracts her by ostentatiously tearing up the sheet of paper on which he had shown her the tree problem. He then shows her another of his set-breaking problems. He writes the number 710 and asks Mrs. A to read it in all possible ways. Most people are not able to break the number set sufficiently to read it as OIL when they turn it upside down. Erickson typically reveals the answer by first asking the patients to make an S near the upside-down 710. If they still don't get it, he has them make the S right in front of the upside-down 710 so it reads SOIL. At that point most people succeed in shifting from the number to the letter set.]

R: This was a typical example of another of your approaches for depotentiating a patient's habitual mental sets to introduce the possibility of experiencing more flexible frames of reference. With the trees and 710 problems, you have patients experience the rigidity of their own mental sets and you give them a bit of training in developing more flexible frames of reference.

E: You always have patients experience as much of themselves and their limiting mental sets as possible within therapy. *The most important thing in therapy is to break up the patients' rigid and limiting mental sets* (Rossi, 1973).

Phobia as a Limited Frame of Reference

E: You can have a numerical frame of reference.

A: Which I definitely do.

E: I know, you work on a computer. Now, what is the proper frame of reference for air turbulence at 30,000 feet up? Is it words or numbers?

A: It's feelings, really.

E: The feelings that you learned on the ground?

A: No. I'm not aware of feelings, having that feeling on the ground.

E: You learned certain feelings of fear on the ground, and you carried them aloft with you. Know what right feelings you should have up there.

A: So are you saying that when I fear an air turbulence, I think only in a fear frame of reference instead of a logical frame of reference?

E: Neither logical nor fear. There is a new frame of reference for you to discover.

A: You mean how I should think of it?

E: Yes. A frame of reference that is really a totally new and different feeling unrelated to any feelings you have had.
Stop to consider, what did the astronauts encounter in space?

A: Total unknowns.

E: Total unknowns! Now what I'm telling you is that air turbulence can't be understood in terms of ground experience, just as the astronauts found out they couldn't understand the absence of gravity. They could pour water up, they could pour water down, or pour it sideways, and I don't know how they could spit.

A: So how do I do that?

E: I don't know how the astronauts learned about no gravity, but they did.

E: She learned fear of heights on the ground and she carried it aloft on a plane where ground fears are inappropriate. In a plane you can hit an air pocket and fall hundreds of feet and it can be a delightful experience. What feelings should you have when you're in the air? Not ground feelings!

R: On the ground it could be a disaster to fall only a few feet.

E: I'm asking her to adopt a frame of reference that is totally new and different.

R: You genuinely don't know how she will experience the new frame of reference. Her conscious mind does not know either. Your job as a therapist is to point out and possibly depotentiate some of the limiting and biasing sets of her conscious mind so her unconscious may have a better opportunity for becoming manifest with the new. This case illustrates the essence of a theory of phobia. Phobic behavior comes about from the problem of using an old frame of reference inappropriately in a new situation. The old frame of reference really doesn't fit, and this lack of fit gives rise to the anxiety, negative affect, and avoidance behavior so characteristic of phobia. The anxiety and avoidance behavior is actually an accurate signal indicating that the patient's old frames of reference need to change. When the patient does not recognize the signal aspect of the anxiety, it is experienced as a negative affect without any appropriate intellectual component: The patient experiences anxiety and fear without knowing why; she has a phobia. We can infer that when a phobia develops in a apparently familiar situation (such as school phobia, agoraphobia, etc.), it means something has changed in the patient's relation to that situation, but this change is not recognized and the appropriate inner adjustments (modifying old frames of reference or creating new ones) have not been made. Phobia is due to a too-limited frame of reference. Its permanent resolution requires insight and expanded frames of reference. This is essentially a new

theory of phobia that is inherent in your work, and you didn't know it, did you?

E: There are a lot of things that I know I don't know.

Further Illustrations of Growth via New Frames of Reference

E: You know the measurements show that the astronauts grew one inch in space, and they lost that inch very promptly after reaching the earth. When children experience a sudden spurt of growth, when a child measures himself against his mother,
you know what happens:
How tall I am!
Everybody in the house knows it.

A: He bumped into things.

E: He was bumping into things!
Striking things with his hands.
The awkward stage is the growing stage.
And he had
to figure out how long his arms were,
how far he stepped.
He had to build a new set of measurements for himself.
Now what set of measurements will you form for turbulence?

[Pause]

You have an opportunity there to find out.

[The senior author now gives other examples of new life experiences requiring the formation of new frames of reference, not merely the use of an old frame inappropriately in a new situation.]

E: The growing age is the awkward age; growing pains.

R: Yes, awkwardness should be applauded as a sign of growth and new learning.

E: You give many examples so that patients are more likely to find one that's personally convincing and actually helps alter their behavior. The only things that I say to you that cling are those that touch upon your experience in some way. You always study your patients for evidence that they are accepting what you say.

Autohypnosis to Facilitate Therapeutic Change: Flexibility in Mental Functioning

A: I am satisfied with not being terrified of flying. To find it enjoyable, that is asking a lot,

I think. You think I will?

E: The astronauts didn't know what on earth it was like to be in space.

A: There is a difference. I can be apprehensive about something unknown, knowing that it is going to turn out OK at the end. That kind of apprehension. But there is no way that I can logically relate to being afraid. I just am. Logically I know I shouldn't be and I know that there is nothing to worry about and I can recite all these statistics and ------

E: And you know how very easily I can put you in a state of terror.

A: Yeah.

E: And wipe it out just as quickly, right?

A: Yeah, the terror.

E: And wipe out your happy feeling, too.

A: Yeah.

E: That is, your fear or your pleasure can be removed and reassumed.

A: Can I do it in advance? I tried hypnotizing myself in a situation and I can't concentrate. Like when we hit turbulence.

E: Try to count from one to twenty.

A: Right now?
From one to twenty? [Mrs. A closes her eyes and evidently goes into trance momentarily. She then opens her eyes, shifts her body, and is obviously awake again.]

E: You didn't get all the way to twenty did you?

A: No.

E: That's right.

[Pause]

And now future accomplishments are future accomplishments.

[Pause]

And they can be enjoyed. [Pause]

A: I was just thinking. I can't wait to get out of here and fly.

E: Well you are at liberty to leave at any time you want to, or stay.

A: That's fantastic. I can't wait to get on an airplane!

E: I facilitate a certain flexibility in mental functioning when I remind her how easily her pleasure and fear can be removed and reassumed.

R: Her residual fears about flying are apparently resolved when you give her the tool of autohypnosis with which to help herself. If trance is conceptualized as an altered state or shift in frames of reference, we can understand how autohypnosis can be particularly useful for phobia or any situation where the patient needs to cope with difficult emotions. Her momentary autohypnotic experience here was enough to let her know that from within she is experiencing a high degree of therapeutic expectancy - so much so that she can't wait to get on a plane!

Selected Shorter Cases: Exercises for Analysis

Uncovering Techniques: Dissociating Intellect and Emotions to Uncover Traumatic Memories

E: In this matter of uncovering techniques I think one of the most important things is to recognize that if your patient has something covered up, she's got it covered up for a very good reason, and you'd better respect that fact. You ask the patients to respect the fact that you personally do not think it needs to be covered up but that you are going to abide by their needs, *their actual needs.* Now you've told them you will abide by their needs, but they don't hear you qualify it to their actual needs.

R: This is an example of indirect suggestion through two-level communication. The first portion of your statement about abiding by their needs is readily accepted by a patient's conscious mind and tends to open a yes or acceptance set for the qualification that follows regarding their actual needs, which may be very different from what they think they are. The unconscious does pick up this qualification (which may be subtly emphasized with a slight vocal intonation or gesture), however, and uses it to initiate an inner process of search for actual needs. This search on an unconscious level may finally result in new insights that will depotentiate the patient's previously limited frames of reference and thus facilitate therapy.

E: Yes. You actually have two issues here: Does it need to be covered up? Can it be uncovered? You then point out to a patient that there are various ways of remembering things. Undoubtedly, when we cover up a memory, we usually cover up a lot more than the memory itself. That is, trauma of a shaved head might be covered up as an uncomfortable memory, but along with that would be covered up the room in which it was done, perhaps the address of that particular place, and other things that happened that year. Does the year need to be covered up? All the other things that happened that year? You thus emphasize that the patient undoubtedly covered up

many things that didn't need to be covered up. So why not uncover every one of those things that are not safe to uncover and be sure to keep covered up the things that are not safe to uncover? You then define the situation as one from which the patient can withdraw at any time. You point out, Suppose you did accidentally uncover something you didn't want uncovered. How long do you think it would take you to cover it up again? That is the little bit of assurance that you always give your patient.

You then point out to a patient that it is perfectly possible to remember the intellectual facts of something but not the emotional content, and vice versa. You point out that once, when you felt downhearted and blue, you couldn't for the life of you figure out why, but there must have been a reason in the back of your mind. You experienced the emotions but you didn't have intellectual content. In recovering a traumatic memory you can uncover deep emotions and not intellectual content. If you want to, you can remember the actual intellectual content; you need not remember whether you felt sad, mad, or glad. It will be just a memory, as if it happened to somebody else.

An example of this was with one of my medical students who was going to flunk out of medical school, he absolutely and irrationally refused to attend the lectures and the clinics on dermatology. He wouldn't open his book on dermatology. He was warned and called up before the dean and told, You're either going to attend dermatology lectures and clinics and study it or you'll flunk out of medicalschool. We can't pass anybody who arbitrarily refuses to take one of the courses, Bob said, I can't. The dean said, What do you mean, you can't, you're going to! Bob meant it, however, he couldn't.

Bob came to me very worried about it. I knew Bob was a very good hypnotic subject and I asked him if I could use him as a demonstration subject to the medical class. He said, Yes. I told him that there had to be some explanation for his peculiar behavior about dermatology. I asked him to spend the next week trying to remember what it was he had forgotten.

Bob spent a week trying to remember and then came to the class. In class I asked, Bob, did you remember what you had forgotten a long time ago? Bob said, How on earth do you go about remembering something you forgot a long time ago? You don't even know where to look! You've forgotten it! It's unavailable, it's unreachable, it's untouchable! It's forgotten - it's gone! I agreed and sent him out of the room so I could raise the question with the class. They all agreed it would be an awfully blind sort of thing to try to find such a memory. Then I called Bob back and induced a deep trance. I told him, You know why you are here. You've been thinking for a whole week about remembering something that you'd forgotten. Have you remembered it? Bob said, No. I said, All right, you are in a deep trance. I would like to explain a few things to you. You know what a jigsaw puzzle is? You can put a jigsaw puzzle together in two ways: You put it together right side up, and then you will know what the picture is; you can put it together reverse side up, and there you have just the back of the jigsaw puzzle. No picture on it - just blank-ness and no meaning, but the puzzle would be together. The picture of the jigsaw puzzle is the intellectual content - the meaningful content of the repressed memory. The back of it is the emotional foundation, and that will be without any picture. It is going to be just the foundation. Now you can put that jigsaw puzzle together by putting two pieces on one corner together, two pieces in the middle together, two pieces in another corner together, two pieces in a third corner, two pieces in a fourth corner, and then, here and there, you can put two or three pieces together. You

can put some of the pieces together face up, some pieces together face down. You can put them all together face down, put them all together face up, but you do what you want to do.

What did he want to do? I didn't know, but that question left the burden of the responsibility upon Bob - namely, that he had a jigsaw puzzle of a repressed memory that he needed to recover and put together meaningfully. I asked Bob, Well, you don't really know what to do. Suppose you haul out from your unconscious just a few little pieces of that unpleasant memory. Bob thought a minute and then perspiration began to form on his forehead. I asked, What is it Bob? He said, I'm feeling sick in a funny sort of way. I don't know what kind of a way. I said, That's fine, so you're feeling sick in a funny sort of way; you don't know in what kind of a way. All right, forget about it. With that Bob developed an amnesia for the material that was making him feel funny. I then continued, Suppose you reach down into your repressions and bring up a few pieces of the picture. Bob did essentially that and said, Well, there is water and there is something green. I suppose that is grass, but that green isn't grass. I said, That is fine, now you shove that down. Now bring up some more pieces of emotion. Bob brought up some more emotion and then said, I'm scared, I'm scared. I want to run, and he was really perspiring and trembling. I said, Shove it down again. Let's bring up a few other picture pieces.

We alternated in that fashion for a while; getting a few associations and then repressing them when the emotion became too threatening. As we got more and more material, Bob began digging up bigger and bigger pieces of emotion so that I would have to bring him out of the trance and let him rest. Bob would take a deep breath and say, I'm all worn out. I don't know what is happening to me. I'm awake, my shirt is all wet, my trousers are wet with perspiration. What has been going on here? I assured him that the medical students in the class were just about as sick as he was of seeing that perspiration spurt out on Bob's forehead each time he'd experience an emotion.

Finally I suggested, Let's put all the blank sides together again and do a complete overhaul. So he put it together again, and you should have seen him trembling and perspiring. He was actually shivering, so periodically I gave him a suggestion to blank it out and rest: Take another deep breath and look at that blank reverse side of the jigsaw puzzle with the amnesic traumatic experience. He said, Whatever is on the other side of that is something awful - it's just awful. I then told him to forget the entire emotional side. We'd turn the jigsaw puzzle over and see it intellectually only, without emotions. He described, Two little boys, about eight or nine years old, they looked like cousins - they're playing in a barn, they are wrestling. Oh! Oh! One is getting mad with the other. Now they are hitting at each other. Now they grabbed some forks, they start stabbing at each other. Oh! Oh! One of them stabbed the other in the leg. That one is running into the house to tell. The one that stabbed him is a little bit afraid. He runs along, too. The boy's father isn't mad; the mother isn't mad; they are calling the doctor. The boy's father makes him sit on a chair to wait. There is the doctor driving in. The doctor is going to stick something in the boy. Oh, my goodness, what a funny thing. Look at that boy's face. He is lying there.

His face is swelling up, his eyes are swelling shut, his skin is turning a funny color, his tongue is so thick, and the doctor is scared. He is getting something else. He' s got - it looks like a needle or a pump of some kind, and he is pumping something into the boy, and now that swelling in the boy's face is getting less, his tongue is getting smaller, he is opening his eyes, and everybody is breathing deeply. The father grabs the other boy and takes him down to the horse trough. The

father sits on the horse trough, hauls the boy over his lap, and starts spanking him, and he is really spanking him hard. The boy is looking down into the horse trough and he sees that green slime on the water and he is crying. There is something awful bad about this, and I don't know what it is. There is something awful bad. I said, Well let one corner of the back of it soak through, and then another corner, let the back of it soak through, soak through, soak through. You should have seen poor Bob as he began uniting the ideational content with the affect. Shuddering, trembling, crying out, horrified, he said I can't stand it.

I again told him to develop a complete amnesia. Take a rest Bob. You have a little more work to do. Maybe if you rest five minutes, we'll have enough strength to do a little more of the work. Then about five minutes later I asked him to continue. He dropped the amnesia until he couldn't stand it any longer, and then another amnesia, a rest, and then again another recovery, until finally he said, That little boy that stabbed the other one is me. That's my cousin, and that was the fork we used for cleaning out the barn, and the doctor comes and gives him an antitetanus shot. He gets an anaphylactic reaction with all that edema, and everybody expects him to die including me. Then the doctor gave him adrenalin and he recovered, and then my father took me down to the horse trough and spanked me. I couldn't even stand the way my cousin looked, and there was my father spanking me and that nasty green slime on the water in the trough - that horrible green slime and that horrible color of my cousin's face. No wonder I couldn't study my dermatology. That was the end of that. No wonder he didn't like dermatology.

Too many therapists try to recover the total experience all at once. In everyday life we frequently notice people with an attitude of indifference. They may have an intellectual appreciation of their position but an emotional indifference. Well, I think that in hypnotherapy we need to recognize the tremendous importance of indifference, detachment, and the possibility of extracting only one fragment here and another fragment there. It was sufficient that Bob recover something and then develop an amnesia, because when he developed an amnesia for any part of it, that was at my request. That was not his own spontaneous involuntary amnesia under pressure. This was something where he was being responsive to suggestion, and therefore the amnesic behavior was under his control. It was just as effective as a repression, but it allowed that traumatic material to be available for examination - and available in varying degrees, in small portions in relation to emotional healing and the ideational content.

The class began at six P.M., and I think it was somewhere around midnight when I finished with him. I cautioned the class to say absolutely nothing to Bob because I knew there was a dermatology class the next afternoon. Everybody cooperated, and when they went to dermatology class, Bob came in casually, matter-of-fact as could be. I told them just to greet him casually and ask him where he is going next but say nothing at all about it. You know it was almost a week before Bob recalled that he was attending dermatology. He just simply took it so-matter-of-factly that he didn't realize he had missed previous lectures and clinics. Now that is an approach I have used with a lot of different patients.

R: Is it necessary to develop a deep trance state for this particular type of thing?

E: It was with Bob, but it's not necessary if you get that state of indifference and ask the person to think of himself more or less as being in the next room undergoing a certain experience. Of course

you can't see it, you can't hear it, but think of yourself as undergoing a certain experience - the experience of recovering a lost traumatic memory, and as you sit here you are not really in a deep trance, you're not really in a medium trance, you are in a light trance. You don't feel like moving, you don't really feel like doing anything, but your mind seems to be rather far away and you are thinking about yourself in the other room - remembering something, and I wonder what part of that memory you're remembering? There you are getting associations, and the patient can start remembering.

R: Your request that the patient simply imagine himself in another room recovering a lost memory is itself an indirect approach to hypnotic induction. You (1) *fixate attention* with that request, and if the patient takes you seriously, you certainly have temporarily (2)*depotentiated his habitual conscious framework.* The patient is thereby engaged in a (3) *search on the unconscious level,* since the conscious mind certainly doesn't know how to do it. The trance induction is further emphasized with your suggestions, You don't feel like moving, you don't really feel like doing anything, but your mind seems to be rather far away. You are utilizing indirect suggestions in the form of not doing, and a dissociation between the personality sitting with you and the mind thinking about yourself in the other room. The patient's own associations and (4) *unconscious processes* then take over and mediate the (5) *hypnotic response* of recovering the lost memory.

Hypnotherapy in Extreme, Sudden, Acute Emotional Disturbances

[*Previously unpublished paper written by the senior author and edited for publication here by the junior author*]

Much has been said and written about the need for intensive searching into the remote past of patients to discover the psychodynamics underlying personality and behavioral disturbances. Alarmist statements have been made about the damage that might result from employing hypnosis in situations of acute emotional distress and disturbances without an adequate knowledge of the patient's past experiences and personality structure. To this author such alarmist statements suggest only lack of knowledge and a sense of personal insecurity when facing problems of stress in others.

The adaptability of hypnosis in meeting critical situations, the ease with which it can be used without altering natural physiological and psychological processes (as contrasted with pharmacological assaults and electric shock), suggest the desirability of its more frequent and ready use in sudden emergency situations. Following are two illustrative accounts, one given in greater detail than the other because of their essential similarity. For the reader's orientation certain general information will be given that was obtained by the author only subsequent to the handling of the acute emergencies.

The patients' presenting problems were handled in the same emergency fashion as one would handle an accident case with acute injuries and a broken leg (that is, first splint the leg and then undertake complete local treatment before taking a detailed history.)

Both of these patients were in their early thirties and both manifested essentially the same behavior, the development of which had, in each instance, been an intense quarrel between husband and wife. Both women were definitely insecure, dependent persons, unstable emotionally and easily rendered tearful. Neither was ever regarded as even latently psychotic, but both were

considered to be passively dependent, emotionally insecure, mildly psychoneurotic persons making reasonably good adjustments in the childless and protected environments in which they lived.

Decondition a Hysterical Catalepsy: Case Report One

This patient was a thirty-three-year old wife of an internist who, with the aid of his partner, practically carried the patient into the senior author's office and placed her in a chair. She sat there rigidly, staring vacantly into space, with fully dilated pupils, in a state of complete unresponsiveness to all stimuli.

The husband explained that she had become hysterical during a quarrel at the office and that she had begun to scream uncontrollably. This had resulted in the husband's partner coming into the office to ascertain what difficulty had arisen. Both had frantically tried to reassure her but could not secure her attention. In desperation they had agreed that perhaps it would be possible to bring her out of it by a sharp slap on the face. This has served to freeze her completely in the state she now presented. They had tried all manner of stimuli to attract her attention, but to no avail. They were alarmed about the bilateral fixed dilation of her pupils because of uneasy feelings about intracranial injury, but felt a bit reassured because the pupils were equally dilated. They had attempted to reduce the pupils by the use of an extremely bright light, but she had stared unblinkingly into the light with no change in her pupils.

Because of the husband's state of emotional distress, he and his partner were excluded from the office, and the husband's request for some suitable intravenous medication to allow her to sleep it off, and his statement that if necessary, I suppose electric shock could be used, were disregarded. The senior author preferred a psychological approach to the patient's psychological reaction in a period of emotional distress. A psychological approach should certainly be regarded as a method of first choice, to be attempted before resorting to drastic assaults upon the patient's body.

Since the two physicians had, at the scene of the inception of the emotional disturbance, tried flashing a powerful light into the patient's eyes, the author decided to capitalize upon this fact. Securing a small blinking light (a child's toy), the senior author placed it at the opposite side of the office so that it would be within her field of vision. Seating himself beside her, he softly repeated a long series of brief, gentle suggestions, synchronizing them with the blinking of the light. (Past experience in research had taught the senior author that conditioned responses can be effectively established even when the subject is not consciously aware of the stimuli.) These suggestions were, Off in the distance, see a light. Now it comes, now it goes. Off in the distance, see a little light. Now it comes, now it goes. With monotonous regularity these suggestions were repeated for about twenty minutes. A slight quivering of her eyelids led to a change in the suggestions to the tripartite suggestion of as it comes - and goes - try harder to see, synchronizing the first and third part to the appearance of the light.

After about five minutes of this triple suggestion, her eyelids began quivering and her pupils started to contract. Further synchronized suggestions were given slightly more urgently: As the light comes, your lids will close; as it goes, they will close more. As it comes, your lids will close;

as it goes, they will close more. Within two minutes the suggestions were changed to, As the light comes, so tired; as it comes, so sleepy; as it comes, eyes close, so tired; as it comes, eyes close, so tired; as it comes, soon asleep; as it comes, soon sound asleep; and sound asleep and sounder asleep, and sound asleep and now sound asleep, There followed, since she responded well, Staying asleep, resting comfortably, repeated a number of times. She was then instructed to rest comfortably, to sleep deeply, to relax so comfortably and completely, to feel so good, so much at rest, so ready to tell the senior author anything he wished to know about, but too tired to be worried, too sleepy to be scared, just softly to tell the senior author whatever he asked, and doing so, just understand everything.

Within forty-five minutes this patient related an informative account of her early youth, when she had seen a neighbor's wife develop an apparently causeless screaming episode that had terminated suddenly in a mute, catatonic, schizophrenic stupor with resulting commitment to a state hospital. She related this as a past unhappy memory that she had forgotten years ago. When she was asked to continue, she showed mild emotional distress and somewhat hesitantly related the circumstances of a quarrel with her husband about a vacation trip. This had caused increasing anger on her part. The trip, as she wished it, would have taken her to her childhood home, but her husband wished to go elsewhere. Realizing that he would have his way, she screamed in futile rage, and then the memory of that neighbor's wife screaming came to her mind. She wondered if I could stop screaming, and that scared me terribly and I kept screaming. Then someone - my husband, I guess - slapped me, and that paralyzed me. I just couldn't see and I couldn't hear. I was just looking helplessly at nothingness, getting more scared all the time. Just thinking about it makes my skin crawl. It won't happen again, will it? She was reassured and asked to continue.

Well, nothing happened forever and ever it seemed, and then I thought I saw a little bright light and I began hearing a voice. At first I couldn't tell what the voice said, but it seemed that I began listening better, and soon I could hear better, and pretty soon I heard you talking to me. I know I didn't know you, but I was tired and sleepy, and some way I knew you would take care of me. You will, won't you?

Again she was reassured and she was asked what next she wanted. Tell my husband. She was asked if she did not think she ought to remember the entire episode when she awakened. Her reply was the inquiry, Will I get scared again? She was answered with, Not unless you want to be. I don't, was her earnest assertion. Accordingly, she was aroused and, with no further instruction, consciously retold the whole story with embarrassment and some slight distress about the extremes of her behavior. She was then asked if it would not be well for her to relate the entire story to her husband. Herreply was, Oh yes,or he will worry about me. She also agreed that her husband's partner could be present when she learned that he had participated in the situation.

Her husband asked, Were you thinking about that neighbor when you insisted on the vacation trip, including going to your old home? Oh, no! I haven't thought of her for years. It's just that I got a letter from Ann [a girlhood friend], that girl I used to know that you didn't like, and I wanted to go back and see her. Further conversation and discussions were not significantly informative. Suffice it to state that the vacation trip did include her desired visit and that her adjustments have improved during the years that have elapsed. Her husband's comment on the correction of his wife's problem was, Well, I suppose it helps people to get things out of their

system, but I'm not sure I would recommend starting it that way.

The entire therapeutic process for this patient required not over two hours, and the passage of about a half dozen years indicates that it was adequate.

Conditioned response; Compound suggestions securing attention and initiating inner searches and responses.

Deconditioning Hysterical Catalepsy: Case Report Two

In the case of the second woman, aged thirty-one, with a personality structure very similar to that of the first patient, and also childless, the immediate emotional difficulty had arisen at the breakfast table. She had timidly told her husband that, on returning from a trip the previous evening, the car had collided with the side of the garage. She had bent the fender slightly and broken the headlight; because of the lateness of the hour, she had not told him because of possible unpleasantness. Her anticipatory fears were justified, as the husband explained in accounting for her condition. I just ranted and raved like a prize idiot, and she got madder and madder, and so did I. She finally grabbed her purse and threw it at me, and it fell open and things spilled out. Her pocket mirror slid along the floor and stopped right where the sun was shining on the floor, and I could see how it reflected the sunlight so that it hit her right in the face. She froze instantly, just froze right like she was, with her face all mad, her eyes glaring, but she just seemed as blind as a bat and as deaf as a stone.

I yelled at her, asking what was the matter, but she didn't make a move. So I shook her and finally she limbered up a little and I brought her in. Did I make her lose her mind, and can you help her?

The man was reassured briefly and dismissed from the office. The woman, who had entered the office with her husband anxiously propelling her like an automaton, now sat listlessly, with her eyes open but apparently unseeing.

After studying her appearance for a few minutes thoughtfully, the senior author touched her gently on the shoulder to attract her attention. The effect was electrifying. Her body jerked to rigidity, and her mouth opened widely as if to scream. Her eyes were wide open, the pupils fully dilated.

The senior author, recalling that she had become frozen stiff when the sunlight had flashed into her eyes, decided to try a technique essentially comparable to the one used above.

Placing the toy blinking light within her field of vision, but keeping it obscured until the suggestions had been phrased, the author began the use of a technique of suggestions similar to the one used with the first patient. A bipartite suggestion was used, synchronizing the first part with the appearance of the light and the second part with the disappearance of the light. Also the two parts were said with distinct but different emphasis, the first part being emphasized as a fact, the second part as a reassurance.

For about fifteen minutes, in repetitious monotony, the senior author carefully stated over and over, You are frightened, but feeling better. As the minutes passed, the second part was more firmly emphasized, until finally she began to relax physically. Then the suggestions were progressively changed in the following fashion: You are less frightened, you are feeling better; you are less frightened, you are feeling better and relaxed; you are feeling still less frightened and more relaxed and better; less and less fright, more and more relaxed, better; just a light fright, so much better; fright going, going, gone, relaxed, comfortable; all better, ready to relax; to sleep, to relax, to sleep; and deeper, deeper and deeper and deeper asleep.

About ten minutes of this graduated change in suggestions resulted in a comfortable, relaxed state of deep hypnosis.

A new suggestion was offered: And now you can look back on last night as if it were last week or even last month - who really cares now? Just feel comfortable and just as if you were another person. Tell me what happened to that young woman in her kitchen that scared her.

With very light urging and only slight emotional display she answered, Light in her eyes, scared, she thought automobile going hit her. Scared, couldn't move. She was told, Now I want you to understand all I say. That young woman was you, and you were scared, but that's all over now. You are here, talking to me about it. Just tell me everything. Just remember I don't know a single *little* thing about it, so be sure to tell me all even if you think parts are *not important* (the italicized words were intended to minimize the whole event without doing so noticeably).

She told a story of a bitter quarrel with her brother and of striking him and turning to run, of how she ran into the street, of how her brother yelled, and then she started to look toward him. It was evening, and a car with glowing headlights was bearing down upon her. She was too paralyzed to move, and she stood staring helplessly even after the car swerved by her. She was forcibly hauled out of the street by her irate father, who soundly spanked both her and her brother. This incident had, to the best of her knowledge, been long forgotten, but the quarrel with her husband over a car, the associated headlight, her assault by throwing her handbag at her husband, and the mirror flashing sunlight in her face had all combined to revivify, in a violently emotional situation, a comparable emotional situation of long-past experience.

The course of handling was similar to that of the other patient. She and her husband were seen for an additional three hours, primarily to meet their current needs. The beneficial results of the therapy, brief as it was, are still persistent.

Fixation of attention, compound suggestions with vocal cues; Pun (light fright); Dissociation initiating inner searches and responses; Two-level communication.

A little needs to be said about the underlying experiential factors and conditionings that long afterward were manifested in the highly disturbed states that developed in these two women. In the limited meanings ascribed to the term by various schools of thought these two problems were clearly psychodynamic in character. But that the handling of the problem therapeutically must necessarily be based on a ritualistic, orthodox, or classical method of approach is, to the senior author, neither reasonable nor profitable. The patients presented a problem that needed to be

handled at once. The problems were remote in origin, recent only in manifestation. To search for those remote origins would have been impossible until the traumatic course of stressful emotional events rendered the patients more accessible and probably more permanently damaged. Past experience with many similar patients suggests the importance of a ready approach to the immediate problem by dealing with it directly.

One can speculate on what would have happened had a pharmacological approach, electric shock, or extensive psychoanalysis been employed. The senior author has seen patients he believed were similar to these so treated with adverse consequences.

In the treatment given these patients it is apparent that hypnosis is a modality that offers possible methods of approach to patients difficult to reach by ordinary interpersonal methods. *Hypnosis also offers the opportunity of dealing with the patient at two levels of awareness,* so that the patient can safely approach a complete understanding of a traumatic experience that was previously repressed as intolerably painful - that is, at an unconscious level of mentation and then at a level of conscious awareness.

An Instance of Aggression Tranformation

[*Previously unpublished paper written by the senior author and edited for publication here by the junior author.*]

From almost the first day in medical school Anne had made herself unpopular with both students and professors. She was always in sight at the classroom door well ahead of time, but she nevertheless entered the classroom from five to twenty minutes late. Each time she would walk across the front of the room, down the far side, and find a seat in the rear of the room. If she had to enter the room from the rear, she walked down the side aisle, crossed the front of the room, and then sought a seat in the rear of the room.

Repeatedly she had been privately and publicly rebuked by her teachers, some patiently, some irately. She always listened courteously, would apologize to them, and then in subsequent classes she would penalize them for the rebuke by being later and more ostentatious. Her classmates came to resent her, some of them intensely and rudely. Nothing availed, and everybody continued to resent this constant irritation by Anne.

A new professor was added to the faculty, and when his student management methods became known, Anne's reformation was gleefully predicted.

The professor's first lecture of that semester of Anne's attendance of his classes was at 8:00 A.M. He arrived at 7:40 A.M. and was greeted cordially by a large number of students, including Anne. One by one the students filed into the classroom and took their seats expectantly. Anne was not among them. The professor closed the classroom door which was at the front of the room, took his place on the podium, and began his lecture. At fifteen minutes past the hour Anne entered. Instantly the professor paused in his lecture, extended his hands palm up to the expectant students, and silently motioned for them to stand. Then he turned toward Anne and silently salaamed, and so did the students, until she had taken her seat. The lecture was then continued as if there had been no interruption.

At the close of the hour the students rushed out to spread the news. Everybody who met Anne - student, secretary, professor, even the dean - salaamed silently, and her entry into any classroom that day was an orgy of silent, respectful salaaming.

Anne was on time for all classes the next day - in fact, she tended to be the first to arrive.

Several months later she sought out the professor to ask for intensive psychotherapy and established excellent rapport with him.

The rationale for this treatment of Anne is rather simple. Her tardiness, whatever its remote origin, had become an aggression, was received as such, continued as such, and was universally regarded by her colleagues and instructors as an intolerable but continuing affront. The entire situation called for an effective aggression against Anne that would eliminate, and thus abolish, her aggression.

By the simple process of a silent salaaming, Anne's aggression was instantly transformed into a totally different kind of thing that offered not an opportunity for aggressive retaliative attack but a joyous participation by all others in the transformation of the aggression. Yet Anne was, in essence, left unscathed as a person, since there still remained with her the control of the aggression. This she promptly manifested the next day by her own abolition of her aggression.

Don't Think of the Baby

This report concerns a problem of brief duration, decidedly acute in character and marked by terrified, obsessional, insistent demands.

The patients were a young couple in their early twenties. Both were attending college, and they had been engaging in sexual relations regularly for nearly a year. They had just discovered that there existed a pregnancy of about two months' duration. Both sets of parents were furious and unforgiving and asserted emphatically that It better be gotten rid of, or no more college (one more year of college for each remained). Extreme and unreasoning emphasis had been placed upon the shame entailed for all relatives and friends. The young couple had planned to marry but not until after graduation from college.

The couple was seriously distressed by their situation and by the parental attitudes that had developed to include no college and no marriage unless you spare us this shame. The father of the young man furnished him sufficient money and advice on where to secure the abortion. A friend of the young man, knowing about the situation and aware of the highly disturbed emotional state of the couple, suggested that they see the senior author and get tranquilized before undertaking the risks of an illegal abortion.

Their distress was greatly augmented when the senior author uncompromisingly discountenanced an abortion. Nor would they listen to the senior author's suggestions of other more reasonable possibilities. For two long hours they insistently repeated demands that the senior author approve the abortion and that he undertake the task himself by using hypnosis to induce physiological

activity, thereby making it legal, and that he prescribe tranquilizing drugs to calm both of them. They expressed fear that their overwrought emotional state, in view of the senior author's lack of cooperation, might cause an abortionist to reject them as too much of a risk, since neither could keep from bursting into hysterical sobs at frequent intervals.
